Part I
User's manual

1 Introduction

The LuaTeX-ja package is a macro package for typesetting high-quality Japanese documents when using LuaTeX.

1.1 Backgrounds

Traditionally, ASCII \texttt{p\TeX}, an extension of \TeX, and its derivatives are used to typeset Japanese documents in \TeX. \texttt{p\TeX} is an engine extension of \TeX: so it can produce high-quality Japanese documents without using very complicated macros. But this point is a mixed blessing: \texttt{p\TeX} is left behind from other extensions of \TeX, especially \texttt{e-\TeX} and pdf\TeX, and from changes about Japanese processing in computers (e.g., the UTF-8 encoding).

Recently extensions of \texttt{p\TeX}, namely up\TeX (Unicode-implementation of \texttt{p\TeX}) and \texttt{\mathcal{e}-p\TeX} (merging of \texttt{p\TeX} and \texttt{\mathcal{e}-\TeX} extension), have developed to fill those gaps to some extent, but gaps still exist.

However, the appearance of Lua\TeX changed the whole situation. With using \texttt{Lua "callbacks"}, users can customize the internal processing of Lua\TeX. So there is no need to modify sources of engines to support Japanese typesetting: to do this, we only have to write Lua scripts for appropriate callbacks.

1.2 Major changes from \texttt{p\TeX}

The LuaTeX-ja package is under much influence of \texttt{p\TeX} engine. The initial target of development was to implement features of \texttt{p\TeX}. However, implementing all feature of \texttt{p\TeX} is impossible, since all process of LuaTeX-ja must be implemented only by Lua and \TeX\ macros. Hence \texttt{LuaTeX-ja is not a just porting of p\TeX}; unnatural specifications/behaviors of \texttt{p\TeX} were not adopted.

The followings are major changes from \texttt{p\TeX}. For more detailed information, see Part III or other sections of this manual.

\textbf{Command names} \texttt{p\TeX} adds several primitives, such as \texttt{\kanjiskip}, \texttt{\prebreakpenalty}, and \texttt{\ifydir}. They can be used as follows:

\begin{verbatim}
\kanjiskip=10pt \dimen0=\kanjiskip 
\tbaselineshift=0.1zw 
\dimen0=\tbaselineshift 
\prebreakpenalty`ぁ=100 
\ifydir ... \f1
\end{verbatim}

However, we cannot use them under Lua\TeX-ja. Instead of them, we have to write as the following.

\begin{verbatim}
\ltjsetparameter{kanjiskip=10pt} \dimen0=\ltjgetparameter{kanjiskip} 
\ltjsetparameter{tbaselineshift=0.1\zw} 
\dimen0=\ltjgetparameter{tbaselineshift} 
\ltjsetparameter{prebreakpenalty={`ぁ,100}} 
\ifnum\ltjgetparameter{direction}=4 ... \f1
\end{verbatim}

Note that \texttt{p\TeX} adds new two useful units, namely \texttt{zw} and \texttt{zh}. As shown above, \texttt{they are changed to \zw and \zh respectively} in Lua\TeX-ja.\footnote{\texttt{Lua\TeX-ja 20200127.0} introduces \texttt{\ltj@zw} and \texttt{\ltj@zh}, which are copy of \texttt{\zw} and \texttt{\zh}.}

\textbf{Linebreak after a Japanese character} In \texttt{p\TeX}, a line break after Japanese character is ignored (and doesn’t yield a space), since line breaks (in source files) are permitted almost everywhere in Japanese texts. However, Lua\TeX-ja doesn’t have this feature completely, because of a specification of Lua\TeX. For the detail, see Section 15.
Spaces related to Japanese characters  The insertion process of glues/kerns between two Japanese characters and between a Japanese character and other characters (we refer glues/kerns of both kinds as JAglue) is rewritten from scratch.

- As LuaTeX’s internal ligature handling is node-based (e.g., of{}fice doesn’t prevent ligatures), the insertion process of JAglue is now node-based.
- Furthermore, nodes between two characters which have no effects in line break (e.g., \special node) and kerns from italic correction are ignored in the insertion process.
- Caution: due to above two points, many methods which did for the dividing the process of the insertion of JAglue in p\TeX{} are not effective anymore. In concrete terms, the following two methods are not effective anymore:
  ちょ{}っと ちょ/

  If you want to do so, please put an empty horizontal box (hbox) between it instead:
  ちょ\hbox{}っと

- In the process, two Japanese fonts which only differ in their “real” fonts are identified.

Directions  From version 20150420.0, LuaTeX-ja supports vertical writing. We implement this feature by using callbacks of LuaTEX; so it must not be confused with \Omega-style direction support of LuaTEX itself. Due to implementation, the dimension returned by \wd, \ht, or \dp depends on the content of the register only. This is major difference with p\TeX{}.

\discretionary  Japanese characters in discretionary break (\discretionary) is not supported.

Greek and Cyrillic letters, and ISO 8859-1 symbols  By default, LuaTeX-ja uses Japanese fonts to typeset Greek and Cyrillic letters. To change this behavior, put \ltjsetparameter{jacharrange={-2,-3}} in the preamble. For the detailed description, see Subsection 4.1.

  From version 20150906.0, characters which belongs both ISO 8859-1 and JIS X 0208, such as ¶ and §, are now typeset in alphabetic fonts.

1.3 Notations

In this document, the following terms and notations are used:

- Characters are classified into following two types. Note that the classification can be customized by a user (see Subsection 4.1).
  - JAchar: standing for characters which is used in Japanese typesetting, such as Hiragana, Katakana, Kanji, and other Japanese punctuation marks.
  - ALchar: standing for all other characters like latin alphabets.

  We say alphabetic fonts for fonts used in ALchar, and Japanese fonts for fonts used in JAchar.

- A word in a sans-serif font with underline (like prebreakpenalty) means an internal parameter for Japanese typesetting, and it is used as a key in \ltjsetparameter command.

- A word in a sens-serif font without underline (like fontspec) means a package or a class of \TeX{}.

- In this document, natural numbers start from zero. \( \omega \) denotes the set of all natural numbers which can be used in \TeX{}.
1.4  About the project

Project Wiki  Project Wiki is under construction.

- https://osdn.jp/projects/luatex-ja/wiki/FrontPage%28en%29 (English)

This project is hosted by OSDN.

2 Getting Started

2.1 Installation

The following packages are needed for the LuaTeX-ja package.

- LuaTeX 1.10.0 (or later) (DVI output \outputmode=8 is not supported.)
- recent luaotfload (v3.1 or later recommended)
- adobemapping (Adobe cmap and pdfmapping files)
- \TeX 2020-02-02 patch level 5 or later (if you want to use LuaTeX-ja with \TeX 2020-02-02)
- etoolbox (if you want to use LuaTeX-ja with \TeX 2020-02-02)
- everyse (only for \TeX 2020-02-02 and 2020-10-01)
- filehook, atbegshi (only for \TeX 2020-02-02)
- ltxcmds, pdftexcmds
- fonts 2.7c (or later)
- Harano Aji fonts (https://github.com/trueroad/HaranoAjiFonts)
  More specifically, HaranoAjiMincho-Regular and HaranoAjiGothic-Medium.

Now LuaTeX-ja is available from CTAN (in the macros/luatex/generic/luatexja directory), and the following distributions:

- \TeX Live (in texmf-dist/tex/luatex/luatexja)
- W32\TeX (in luatexja.tar.xz)
- MiKTeX (in luatexja.tar.xz in W32\TeX).

Harano Aji fonts are also available in these distributions (haranoaji in \TeX Live and MiKTeX, and luatexja.tar.xz in W32\TeX).

■ HarfBuzz and Lua\TeX-ja Using Lua\TeX-ja with LuaHB\TeX (Lua\TeX integrated with HarfBuzz) is not well tested. Maybe documents can typeset without an error, but with unwanted results (especially, vertical typesetting and \CID).

Especially, We don’t recommend defining a Japanese font with HarfBuzz, by specifying Render=Harfbuzz etc. (fonts2spec) or mode=harf (otherwise).

■ Manual installation

1. Download the source, by one of the following method. At the present, Lua\TeX-ja has no stable release.

- Clone the Git repository by
  $ git clone git://git.osdn.jp/gitroot/luatex-ja/luatexja.git

- Download the tar.gz archive of HEAD in the master branch from
  http://git.osdn.jp/view?p=luatex-ja/luatexja.git;a=snapshot;h=HEAD;sf=tgz.

Note that the master branch, and hence the archive in CTAN, are not updated frequently; the forefront of development is not the master branch.

2. Extract the archive. You will see src/ and several other sub-directories. But only the contents in src/ are needed to work Lua\TeX-ja.
3. If you downloaded this package from CTAN, you have to run following commands to generate classes:

```bash
$ cd src
$ lualatex ltjclasses.ins
$ lualatex ltjsclasses.ins
$ lualatex ltjltxdoc.ins
```

4. Copy all the contents of `src/` into one of your `TEXMF` tree. `TEXMF/tex/luatex/luatexja/` is an example location. If you cloned entire Git repository, making a symbolic link of `src/` instead copying is also good.

5. If `mktexlsr` is needed to update the file name database, make it so.

### 2.2 Cautions

For changes from `p\TeX`, see Subsection 1.2.

- The encoding of your source file must be UTF-8. Other encodings, such as EUC-JP or Shift-JIS, are not supported.

- Lua\TeX-ja is very slower than `p\TeX`, and uses a lot of memory.

- **(Outdated) note for MiK\TeX users** Lua\TeX-ja requires that several CMap files\(^2\) must be found from Lua\TeX. Strictly speaking, those CMaps are needed only in the first run of Lua\TeX-ja after installing or updating. But it seems that MiK\TeX does not satisfy this condition, so you will encounter an error like the following:

  ```
  ! LuaTeX error ...iles (x86)/MiKTeX 2.9/tex/luatex/luatexja/ltj-rmlgbm.lua
  bad argument #1 to 'open' (string expected, got nil)
  ```

  If so, please execute a batch file which is written on the Project Wiki (English). This batch file creates a temporary directory, copy CMaps in it, run a test file which loads Lua\TeX-ja in this directory, and finally delete the temporary directory.

- Note that when Lua\TeX-ja is loaded in plain Lua\TeX, we cannot use color specification on font loading, such as

  ```latex
  \font\hoge=lmroman10-regular.otf:color=FF0000 % \font primitive
  ```

  This is because codes for shifting baseline in math mode (Lua\TeX-ja) collide with and prevents loading codes for font color (`luaotfload`) in these environments. **We recommend to use \TeX 2020-02-02 (or later)**, since we can avoid this collision in there.

### 2.3 Using in plain \TeX

To use Lua\TeX-ja in plain \TeX, simply put the following at the beginning of the document:

```
\input luatexja.sty
```

This does minimal settings (like `ptex.tex`) for typesetting Japanese documents:

- The following 12 Japanese fonts are preloaded:

<table>
<thead>
<tr>
<th>direction</th>
<th>classification</th>
<th>font name</th>
<th>“10 pt”</th>
<th>“7 pt”</th>
<th>“5 pt”</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>yoko</em> (horizontal)</td>
<td><em>mincho</em> gothic</td>
<td>HaranoAjiMincho-Regular</td>
<td>\tenmin</td>
<td>\sevemin</td>
<td>\fivemin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HaranoAjiMincho-Medium</td>
<td>\tengt</td>
<td>\seventgnt</td>
<td>\fivegt</td>
</tr>
<tr>
<td><em>tate</em> (vertical)</td>
<td><em>mincho</em> gothic</td>
<td>HaranoAjiMincho-Regular</td>
<td>\tentmin</td>
<td>\seventmin</td>
<td>\fivetmin</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HaranoAjiMincho-Medium</td>
<td>\tentgt</td>
<td>\seventgt</td>
<td>\fivetgt</td>
</tr>
</tbody>
</table>

The "default" Japanese fonts (and JFMs for them) can be modified by defining `\l@stdmcfont etc. before one inputs `\luatexja.sty (Subsection 8.3).

A character in an alphabetic font is generally smaller than a Japanese font in the same size. So actual size specification of these Japanese fonts is in fact smaller than that of alphabetic fonts, namely scaled by 0.962216.

- The amount of glue that are inserted between a `\textjchar and an `\texta char (the parameter `\kanjiskip) is set to

\[(0.25 \cdot 0.962216 \cdot 10 \text{ pt})^{-1} = 2.40554 \text{ pt}.

\]

\[2.40554 \text{ pt} - 1 \text{ pt} = 2.40554 \text{ pt}.

2.4 Using in `{\LaTeX}

Using in `{\LaTeX}2\epsilon is basically same. To set up the minimal environment for Japanese, you only have to load `\luatexja.sty:

```
\usepackage{luatexja}
```

It also does minimal settings (counterparts in `{pLaTeX are `\plfonts.dtx and `\pldefs.ltx).

- Font encodings for Japanese fonts are `\textjtexty3 (for horizontal direction) and `\textjtextt3 (for vertical direction).

- Traditionally, Japanese documents use only two families: `\textjmincho (明朝体) and `\textjgothic (ゴシック体). `\textjmincho is used in the main text, while `\textjgothic is used in the headings or for emphasis.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|}
\hline
\textbf{classification} & \textbf{commands} & \textbf{family} \\
\hline
`\textjmincho (明朝体) & `\textmc{...} `\mcfamily ... & `\mcdefault \\
`\textjgothic (ゴシック体) & `\textgt{...} `\gtfamily ... & `\gtdefault \\
(Japanese counterpart for typewriter font) & & `\jttdefault \\
\hline
\end{tabular}
\end{table}

Here `\textjdefault specifies the Japanese font family in `\textjverb or `\textjverbatim environment, and its default value is `\mcdefault (mincho family).\footnote{When `\ltjclasses classes are used, or `\luatexja-fontspec (or `\luatexja-preset) is loaded with `\match option, `\textttfamily changes the current Japanese font amily to `\jttdefault. These classes and packages also redefine `\jttdefault to `\gtdefault (gothic family).}

- By default, the following fonts are used for these two families.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
\textbf{classification} & \textbf{family} & `\textmdseries & `\textbfseries & scale \\
\hline
`\textjmincho (明朝体) & mc & HaranoAjiMincho-Regular & HaranoAjiGothic-Medium & 0.962216 \\
`\textjgothic (ゴシック体) & gt & HaranoAjiGothic-Medium & HaranoAjiGothic-Medium & 0.962216 \\
\hline
\end{tabular}
\end{table}

- Note that the bold series (series `\textjbx or `\textj\textbf) in both family are same as the medium series of gothic family. There is no italic nor slanted shape for these `\textjmc and `\textjgt.

- From version 20181102.0, one can specifies `\textjdisablejfam option at loading `\textjLaTeX-ja. This option prevents loading a patch for `{\LaTeX}, which are needed to support Japanese characters in math mode.

Without `\textjdisablejfam option, one can typeset Japanese characters in math mode as `$\textj$` (see Page 11) as before. Japanese characters in math mode are typeset by the font family `\textjmc.

- If you use the `\textjbeamer class with the default font theme (which uses sans serif fonts) and with LuaTeX-ja, you might want to change default Japanese fonts to the gothic family. The following line changes the default Japanese font family to it:

```
\renewcommand{\kanjifamilydefault}{\gtdefault}
```

However, above settings are not sufficient for Japanese-based documents. To typeset Japanese-based documents, you are better to use class files other than article.cls, book.cls, and so on. At the present, Lua\TeX-ja has the counterparts of jclasses (standard classes in \TeX) and jsclasses (classes by Haruhiko Okumura), namely, ltjclasses\footnote{ltjarticle.cls, ltjbook.cls, ltjreport.cls, ltjarticle.cls, ltjbook.cls, ltjreport.cls. The latter ltjt*.cls are for vertically written Japanese documents.} and ltjsclasses\footnote{ltjsarticle.cls, ltjsbook.cls, ltjsreport.cls, ltjsarticle.cls, ltjsbook.cls, ltjsreport.cls. The latter ltjskiyou.cls.}.

Original jsclasses use \mag primitive to set the main document font size. However, Lua\TeX does not support \mag in PDF output, so ltjsclasses uses the nomag* option\footnote{Same effect as the BXjscls classes (by Takayuki Yato) and jsclasses. However, these classes uses only \TeX code, but ltjsclasses uses Lua code.} by default to set the main font size. If this causes some unexpected behavior, specify nomag option in \documentclass.

\section*{geometry package and classes for vertical writing} It is well-known that the geometry package produces the following error, when classes for vertical writing is used:

\begin{verbatim}
! Incompatible direction list can't be unboxed.
@begindvi ->\unvbox @begindvibox
\global \let @begindvi \empty
\end{verbatim}

Now, Lua\TeX-ja automatically applies the patch lltjp-geometry to the geometry package, when the direction of the document is \textit{tate} (vertical writing). This patch lltjp-geometry also can be used in p\TeX; for the detail, please refer lltjp-geometry.pdf (Japanese).

\section{Changing Fonts}
\subsection{plain \TeX and \LaTeX
2\epsilon} \begin{itemize}
\item \textbf{plain \TeX} To change Japanese fonts in plain \TeX, you must use the command \jfont and \tfont. So please see Subsection 8.1.
\item \textbf{\LaTeX\ 2\epsilon (NFSS2)} For \LaTeX\ 2\epsilon, Lua\TeX-ja adopted most of the font selection system of \p\LaTeX\ 2\epsilon (in plfonts.dtx).
\end{itemize}

<table>
<thead>
<tr>
<th>encoding</th>
<th>family</th>
<th>series</th>
<th>shape</th>
<th>selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alphabetic fonts</td>
<td>\romanencoding</td>
<td>\romanfamily</td>
<td>\romanseries</td>
<td>\romanshape</td>
</tr>
<tr>
<td>Japanese fonts</td>
<td>\kanjiencoding</td>
<td>\kanjifamily</td>
<td>\kanjiseries</td>
<td>\kanjishape</td>
</tr>
<tr>
<td>both</td>
<td></td>
<td></td>
<td>\fontseries</td>
<td>\fontshape</td>
</tr>
<tr>
<td>auto select</td>
<td>\fontencoding</td>
<td>\fontfamily</td>
<td>\fontseries</td>
<td>\fontshape</td>
</tr>
</tbody>
</table>

- \fontfamily, \fontseries, and \fontshape try to change attributes of Japanese fonts, as well as those of alphabetic fonts. Of course, \selectfont is needed to select current text fonts.

Note that \fontshape always changes current alphabetic font shape, but it does \textit{not} change current Japanese font shape if the target shape is unavailable for current Japanese encoding/family/series. For the detail, see Subsection 11.2.

- \fontencoding\{\langle encoding\rangle\} changes the encoding of alphabetic fonts or Japanese fonts depending on the argument. For example, \fontencoding\{JY3\} changes the encoding of Japanese fonts to JY3, and \fontencoding\{T1\} changes the encoding of alphabetic fonts to T1. \fontfamily also changes the current Japanese font family, the current alphabetic font family, or both. For the detail, see Subsection 11.2.

- For defining a Japanese font family, use \DeclareKanjiFamily instead of \DeclareFontFamily. (In previous version of Lua\TeX-ja, using \DeclareFontFamily didn't cause any problem. But this no longer applies the current version.)

- Defining a Japanese font shape can be done by usual \DeclareFontShape:

\begin{verbatim}
\DeclareFontShape\{JY3\}\{mc\}\{b\}\{n\}\{<-> s*HaranoAjiMincho--Bold:ljf=ujis;-kern\}{% Harano Aji Mincho Bold
\end{verbatim}
Table 1. Commands of luatexja-fontspec

</tr>
</tbody>
</table>

### Japanese characters in math mode
Since \TeX supports Japanese characters in math mode, there are sources like the following:

1. $f_\text{高温}$ ($f_{\text{high temperature}}$).
2. $y=(x-1)^2+2 \text{ よって } y>0$
3. $5 \in \text{素} := \{p \in \mathbb{N} : \text{p is a prime}\}$.

We (the project members of Lua\TeX-ja) think that using Japanese characters in math mode are allowed if and only if these are used as identifiers. In this point of view,

- The lines 1 and 2 above are not correct, since “高温” in above is used as a textual label, and “よって” is used as a conjunction.
- However, the line 3 is correct, since “素” is used as an identifier.

Hence, in our opinion, the above input should be corrected as:

1. $f_\text{高温}$ ($f_{\text{high temperature}}$).
2. $y=(x-1)^2+2 \text{ よって } y>0$
3. $5 \in \text{素} := \{p \in \mathbb{N} : \text{p is a prime}\}$.

We also believe that using Japanese characters as identifiers is rare, hence we don’t describe how to change Japanese fonts in math mode in this chapter. For the method, please see Subsection 8.6.

When Lua\TeX-ja is loaded with disablejmath option, one cannot write Japanese characters in math mode as $\text{素}$.$ At that case, one have to use \mbox (or \text in the amsmath package).

#### 3.2 luatexja-fontspec package

To use the functionality of the fontspec package to Japanese fonts, it is needed to load the luatexja-fontspec package in the preamble, as follows:

```
\usepackage{luatexja-fontspec}
```

This luatexja-fontspec package automatically loads luatexja and fontspec packages, if needed.

In the luatexja-fontspec package, several commands are defined as counterparts of original commands in the fontspec package (see Table 1):

- The package option of luatexja-fontspec are the followings:

  match
  If this option is specified, usual family-changing commands such as \rmfamily, \textrm, \sffamily, ... also change Japanese font family.

  pass=\langle opts \rangle
  (Obsoleted) Specify options \langle opts \rangle which will be passed to the fontspec package.
Override the ratio of the font size of Japanese fonts to that of alphabetic fonts. The default value is determined as follows:

- The value of \texttt{Cjascale} is used, if this control sequence is already defined.
- It is calculated automatically from the current Japanese font at the loading of the package, if \texttt{Cjascale} is not defined.

\texttt{Cjascale} is defined in \texttt{ltjclasses} and \texttt{ltjsclasses}.

All other options listed above are simply passed to the fontspec package. This means that two lines below are equivalent, for example.

\begin{verbatim}
\usepackage[no-math]{fontspec}\usepackage[fontspec]{luatexja-fontspec}
\end{verbatim}

Note that kerning information in a font is not used (that is, kern feature is set off) by default in these seven (or eight) commands. This is because of the compatibility with previous versions of Lua\TeX-ja (see 8.1).

Below is an example of \texttt{\jfontspec}.

\begin{verbatim}
1 \jfontspec[CJKShape=NLC]{HaranoAjiMincho-Regular}
JIS~X~0213:2004 →辻鯵
2 \jfontspec[CJKShape=JIS1990]{HaranoAjiMincho-Regular}
JIS~X~0208-1990 →辻鯵
3 \jfontspec[CJKShape=JIS1978]{HaranoAjiMincho-Regular}
JIS~C~6226-1978 →辻鰺
\end{verbatim}

\section{Presets of Japanese fonts}

With luatexja-preset package, one use one of “preset” to simplify Japanese font setting. For details of package options, and those of each presets, please see Subsection 13.6. The following presets are defined:

- \texttt{haranoaji}, \texttt{hiragino-pro}, \texttt{hiragino-pron}, \texttt{ipa}, \texttt{ipa-hg}, \texttt{ipaex}, \texttt{ipaex-hg}, \texttt{kozuka-prő}, \texttt{kozuka-prón}, \texttt{mora-mobo}, \texttt{mora-mobo-ex}, \texttt{bizud}, \texttt{morisawa-prón}, \texttt{mora-mobo}, \texttt{ms}, \texttt{ms-hg}, \texttt{noembed}, \texttt{noto-otc}, \texttt{noto-otf}, \texttt{sourcehan}, \texttt{sourcehan-jp}, \texttt{ume}, \texttt{yu-osx}, \texttt{yu-win}, \texttt{yu-win10}

For example, this document loads luatexja-preset package by

\begin{verbatim}
\usepackage[haranoaji]{luatexja-preset}
\end{verbatim}

which means that Harano Aji fonts will be used in this document.

\section{\texttt{CID}, \texttt{UTF}, and macros in \texttt{japanese-otf} package}

Under p\TeX, japanese-otf package (developed by Shuzaburo Saito) is used for typesetting characters which is in Adobe-Japan1-6 CID but not in JIS X 0208. Since this package is widely used, Lua\TeX-ja supports some of functions in the japanese-otf package, as an external package luatexja-otf.

\begin{verbatim}
森UTF{9D07}外とCID{13966}田百UTF{9592}とが
森鷗外と内田百間とが髙島屋に
\end{verbatim}

\section{Changing Internal Parameters}

There are many internal parameters in Lua\TeX-ja. And due to the behavior of Lua\TeX, most of them are not stored as internal register of \TeX, but as an original storage system in Lua\TeX-ja. Hence, to assign or acquire those parameters, you have to use commands \texttt{\ltjsetparameter} and \texttt{\ltjgetparameter}.
Table 2. Characters in predefined character range 8.

| U+00B4 | Spacing acute |
| U+00B7 | Multiplication sign |

Table 3. Unicode blocks in predefined character range 1.

| U+0080–U+00FF | Latin-1 Supplement |
| U+0100–U+017F | Latin Extended-A |
| U+0180–U+024F | Latin Extended-B |
| U+0250–U+02AF | IPA Extensions |
| U+02B0–U+02FF | Spacing Modifier Letters |
| U+0300–U+036F | Combining Diacritical Marks |
| U+1E00–U+1EFF | Latin Extended Additional |

4.1 Range of JAchars

LuaTeX-ja divides the Unicode codespace U+0080–U+10FFFF into character ranges, numbered 1 to 217. The grouping can be (globally) customized by \ltjdefcharrange. The next line adds whole characters in Supplementary Ideographic Plane and the character “漢” to the character range 100.

\ltjdefcharrange{100}{"20000-"2FFFF, "漢"}

A character can belong to only one character range. For example, whole SIP belong to the range 4 in the default setting of LuaTeX-ja, and if one executes the above line, then SIP will belong to the range 100 and be removed from the range 4.

The distinction between ALchar and JAchar is performed by character ranges. This can be edited by setting the jacharrange parameter. For example, the code below is just the default setting of LuaTeX-ja, and it sets:

- a character which belongs character ranges 1, 4, 5, and 8 is ALchar,
- a character which belongs character ranges 2, 3, 6, 7, and 9 is JAchar.

\ltjsetparameter{jacharrange={-1, +2, +3, -4, -5, +6, +7, -8, +9}}

The argument to jacharrange parameter is a list of non-zero integer. Negative integer \(-n\) in the list means that “each character in the range \(n\) is an ALchar”, and positive integer \(+n\) means that “... is a JAchar”.

Note that characters U+0000–U+007F are always treated as an ALchar (this cannot be customized).

■ Default character ranges LuaTeX-ja predefines nine character ranges for convenience. They are determined from the following data:

- Blocks in Unicode 12.0.0.
- The Adobe-Japan1-UCS2 mapping between a CID Adobe-Japan1- and Unicode.
- The PXbase bundle for upTeX by Takayuki Yato.

Now we describe these nine ranges. The superscript "J" or "A" after the number shows whether each character in the range is treated as JAchars or not by default. These settings are similar to the prefercjk settings defined in PXbase bundle. Any characters equal to or above U+0080 which does not belong to these eight ranges belongs to the character range 217.

Range 8J The intersection of the upper half of ISO 8859-1 (Latin-1 Supplement) and JIS X 0208 (a basic character set for Japanese). The character list is indicated in Table 2.

Range 1A Latin characters that some of them are included in Adobe-Japan1-7. This range consists of the Unicode ranges indicated in Table 3, except characters in the range 8 above.

Range 2J Greek and Cyrillic letters. JIS X 0208 (hence most of Japanese fonts) has some of these characters.

- U+0370–U+03FF: Greek and Coptic
- U+0400–U+04FF: Cyrillic
- U+1F00–U+1FFF: Greek Extended

**Range 3** Miscellaneous symbols. The block list is indicated in Table 4.

**Range 9** The intersection of the “General Punctuation” block (U+2000–U+206F) and Adobe-Japan1-7 character collection. This character range characters in Table 5.

**Range 4** Characters usually not in Japanese fonts. This range consists of almost all Unicode blocks which are not in other predefined ranges. Hence, instead of showing the block list, we put the definition of this range itself.

```latex
\ltdefcharrange{4}{% 
  "500-"10FF, "1200-"1DFF, "2440-"255F, "27C0-"28FF, "2A00-"2AFF, 
  "2C00-"2E7F, "4D00-"4DFF, "A400-"A95F, "A980-"ABFF, "E000-"FF8F, 
  "F800-"FE0F, "FE20-"FE2F, "FE70-"FEFF, "10000-"1AFF, "1B170-"1FFF, 
  "1F300-"1FFFF, ... (and characters in U+2000–U+206F which are not in range 9) 
} % non-Japanese
```

**Range 5** Surrogates and Supplementary Private Use Areas.

**Range 6** Characters used in Japanese. The block list is indicated in Table 6.

**Range 7** Characters used in CJK languages, but not included in Adobe-Japan1-7. The block list is indicated in Table 7.

**Notes on U+0080–U+00FF** You should treat characters in textttU+0080–U+00FF as **Alchar**, when you use traditional 8-bit fonts, such as the marvosym package.
Table 6. Unicode blocks in predefined character range 6.

| \begin{tabular}{c|c|c} \hline Unicode Blocks & \begin{tabular}{c} Character Range \end{tabular} & \begin{tabular}{c} Description \end{tabular} \\ \hline U+2460–U+24FF & Enclosed Alphanumerics & U+2E80–U+2EFF CJK Radicals Supplement \\ U+2800–U+28FF & CJK Symbols and Punctuation & U+3080–U+30FF Hiragana \\ U+30AB–U+30FF & Katakana & U+3190–U+319F Kanbun \\ U+31FB–U+31FF & Katakana Phonetic Extensions & U+3200–U+32FF Enclosed CJK Letters and Months \\ U+3500–U+35FF & CJK Compatibility & U+3400–U+34FF CJK Unified Ideographs Ext-A \\ U+4E00–U+9FFF & CJK Unified Ideographs & U+5F00–U+5F4F CJK Compatibility Ideographs \\ U+FE10–U+FFEF & Vertical Forms & U+FE30–U+FE4F CJK Compatibility Forms \\ U+FE60–U+FE9F & Small Form Variants & U+FF00–U+FFF F Fullwidth Forms \\ U+1100–U+11FF & Kana Supplement & U+1B00–U+1B1F Kana Extended-A \\ U+1F00–U+1FFF & Enclosed Alphanumeric Supp. & U+1F10–U+1F1F Enclosed Ideographic Supp. \\ U+20000–U+20FF & \begin{tabular}{c} \begin{tabular}{c} Supp. Ideographic Plane \end{tabular} \end{tabular} & U+30000–U+30FF \begin{tabular}{c} \begin{tabular}{c} (Supp. Ideographic Plane) \end{tabular} \end{tabular} \\ U+31FF–U+4E00 & Variation Selectors Supp. & U+5F00–U+7EFF \begin{tabular}{c} \begin{tabular}{c} (Tert. Ideographic Plane) \end{tabular} \end{tabular} \\ \hline \end{tabular} |

Table 7. Unicode blocks in predefined character range 7.

| \begin{tabular}{c|c|c} \hline Unicode Blocks & \begin{tabular}{c} Character Range \end{tabular} & \begin{tabular}{c} Description \end{tabular} \\ \hline U+1100–U+11FF & Hangul Jamo & U+2F80–U+2FFD Kangxi Radicals \\ U+2F80–U+2FFF & Ideographic Description Characters & U+3100–U+312F Bopomofo \\ U+3130–U+318F & Hangul Compatibility Jamo & U+31AB–U+31BF Bopomofo Extended \\ U+5F00–U+5F4F & CJK Strokes & U+5F50–U+5F9F Yi Syllables \\ U+6800–U+9FFF & Yi Radicals & U+9000–U+9FFF Hangul Jamo Extended-A \\ U+AC00–U+FAFF & Hangul Syllables & U+F900–U+F9FF Hangul Jamo Extended-B \\ \hline \end{tabular} |

For example, \Fromny which is provided by the marvosym package has the same codepoint as § (U+00A7). Hence, as previous versions of Lua\TeX-ja, if these characters are treated as \texttt{JAchar}, then \Fromny produces “§” (in a Japanese font). To avoid such situations, the default setting of Lua\TeX-ja is changed in version 20150906.0 so that all characters U+0080–U+00FF are treated as \texttt{ALchar}.

If you want to output a character as \texttt{ALchar} and \texttt{JAchar} regardless the range setting, you can use \texttt{\jtjachar} and \texttt{\jtjaichar} respectively, as the following example.

\begin{verbatim}
\jtfamily\large % default, \texttt{ALchar}, \texttt{JAchar} \\
§, \jtjachar§, \jtjaichar§\} % default: \texttt{ALchar} \\
α, \jtjacharα, \jtjaicharα % default: \texttt{JAchar} \\
\end{verbatim}

4.2 \texttt{kanjiskip} and \texttt{xkanjiskip}

\texttt{JAglue} is divided into the following three categories:

- Glues/kerns specified in JFM. If \texttt{\inhibitglue} is issued around a \texttt{JAchar}, this glue will not be inserted at the place.
- The default glue which inserted between two \texttt{JAchars} (\texttt{kanjiskip}).
- The default glue which inserted between a \texttt{JAchar} and an \texttt{ALchar} (\texttt{xkanjiskip}).

The value (a skip) of \texttt{kanjiskip} or \texttt{xkanjiskip} can be changed as the following. Note that only their values at the end of a paragraph or a hbox are adopted in the whole paragraph or the whole hbox.

\begin{verbatim}
\jtjsetparameter{kanjiskip={0pt plus 0.4pt minus 0.4pt}, \\
xkanjiskip={0.25\zw plus 1pt minus 1pt}}
\end{verbatim}

Here \texttt{\zw} is a internal dimension which stores fullwidth of the current Japanese font. This \texttt{\zw} can be used as the unit \texttt{\zw} in \texttt{\pT\X}.

The value of these parameter can be get by \texttt{\jtjgetparameter}. Note that the result by \texttt{\jtjgetparameter} is not the internal quantities, but a string (hence \texttt{\the} the cannot be prefixed).

\begin{verbatim}
\begin{verbatim}
\jtjgetparameter{kanjiskip}, \texttt{\space} % kanjiskip: 0.0pt plus 0.4pt minus 0.5pt, \\
xkanjiskip: \texttt{\space} % xkanjiskip: 2.40553pt plus 1.0pt minus 1.0pt
\end{verbatim}
\end{verbatim}

It may occur that JFM contains the data of “ideal width of \texttt{kanjiskip}” and/or “ideal width of \texttt{xkanjiskip}”. To use these data from JFM, set the value of \texttt{kanjiskip} or \texttt{xkanjiskip} to \texttt{\maxdimen} (these “ideal width” cannot be retrieved by \texttt{\jtjgetparameter}).
4.3 Insertion setting of \texttt{xkanjiskip}

It is not desirable that \texttt{xkanjiskip} is inserted into every boundary between \texttt{JAchar}s and \texttt{ALchar}s. For example, \texttt{xkanjiskip} should not be inserted after opening parenthesis (e.g., compare “(あ)” and “(あ)”). \texttt{LuaTeX-ja} can control whether \texttt{xkanjiskip} can be inserted before/after a character, by changing \texttt{jaxspmode} for \texttt{JAchar}s and \texttt{alxspmode} parameters \texttt{ALchar}s respectively.

\begin{verbatim}
\ltjsetparameter{jaxspmode={`あ,preonly},
  alxspmode=`!,postonly}}
p あ い u
\end{verbatim}

The second argument \texttt{preonly} means that the insertion of \texttt{xkanjiskip} is allowed before this character, but not after. The other possible values are \texttt{postonly}, \texttt{allow}, and \texttt{inhibit}.

\texttt{jaxspmode} and \texttt{alxspmode} use a same table to store the parameters on the current version. Therefore, line 1 in the code above can be rewritten as follows:

\begin{verbatim}
\ltjsetparameter{alxspmode={`あ,preonly}, jaxspmode=`!,postonly}}
\end{verbatim}

One can use also numbers to specify these two parameters (see Subsection 9.1).

If you want to enable/disable all insertions of \texttt{kanjiskip} and \texttt{xkanjiskip}, set \texttt{autospacing} and \texttt{autoxspacing} parameters to true/false, respectively.

4.4 Shifting the baseline

To make a match between a Japanese font and an alphabetic font, sometimes shifting of the baseline of one of the pair is needed. In \texttt{pd\TeX}, this is achieved by setting \texttt{\ybaselineshift} (or \texttt{\tbaselineshift}) to a non-zero length (the baseline of \texttt{ALchar} is shifted below). However, for documents whose main language is not Japanese, it is good to shift the baseline of Japanese fonts, but not that of alphabetic fonts. Because of this, \texttt{LuaTeX-ja} can independently set the shifting amount of the baseline of alphabetic fonts and that of Japanese fonts.

Here the horizontal line in the below example is the baseline of a line.

\begin{verbatim}
\vrule width 150pt height 0.2pt depth 0.2pt \hskip-120pt
\ltjsetparameter{yjabaselineshift=0pt,
  ylabaselineshift=0pt, ylabaselineshift=0pt}abcあいう
\ltjsetparameter{yjabaselineshift=5pt,
  ylabaselineshift=0pt}abcあいう
\end{verbatim}

There is an interesting side-effect: characters in different size can be vertically aligned center in a line, by setting two parameters appropriately. The following is an example (beware the value is not well tuned):

\begin{verbatim}
\vrule width 150pt height 4.417pt depth -4.217pt \% \kern-150pt
\large \texttt{xyz}漢字
{\scriptsize  \ltjsetparameter{yjabaselineshift=-1.757pt,
  ylabaselineshift=-1.757pt}
  漢字\texttt{xyz}あいう
  }あいうabc
\end{verbatim}

Note that setting positive \texttt{ylabaselineshift} or \texttt{talbaselineshift} parameters does not increase the depth of one-letter syllable \texttt{p} of \texttt{Alchar}, if its left-protrusion (\texttt{\lpcode}) and right-protrusion (\texttt{\rpcode}) are both non-zero. This is because

- These two parameters are implemented by setting \texttt{yoffset} field of a glyph node, and this does not increase the depth of the glyph.
• To cope with the above situation, Lua\TeX-ja automatically supplies a rule in every syllable.

• However, we cannot use this “supplying a rule” method if a syllable comprises just one letter whose \texttt{\ldcode} and \texttt{\rdcode} are both non-zero.

This problem does not apply for \texttt{\yjabaselineshift} nor \texttt{\tjabaselineshift}, because a \texttt{JAchar} is encapsulated by a horizontal box if needed.

4.5 \textit{kinsoku} parameters and OpenType features

Among parameters which related to Japanese word-wrapping process (\textit{kinsoku shori}),

\texttt{jaxspmode}, \texttt{alxspmode}, \texttt{prebreakpenalty}, \texttt{postbreakpenalty} and \texttt{kcatcode}

are stored by each character codes.

OpenType font features are ignored in these parameters. For example, a fullwidth katakana “ア” on line 10 in the below input is replaced to its halfwidth variant “ア”, by \texttt{hwid} feature. However, the penalty inserted after it is 10 which is the \texttt{postbreakpenalty} of “ア”, not 20.

\begin{verbatim}
1 \ltjsetparameter{postbreakpenalty=\{ア, 10\}}
2 \ltjsetparameter{postbreakpenalty=\{7, 20\}}
3 \\newcommand\showpostpena[1]{%\leavevmode\setbox0=\hbox{#1\hbox{}}}\setbox0=\lastbox\the\lastpenalty}
4 \showpostpena{ア}, \showpostpena{ア},
5 {\addjfontfeatures{CharacterWidth=Half}\showpostpena{ア}}
\end{verbatim}

ア 10, ア 20, ア 10
Part II

Reference

5 \catcode in Lua\TeX-ja

5.1 Preliminaries: \catcode in \p\TeX and up\TeX

In \p\TeX and up\TeX, the value of \catcode determines whether a Japanese character can be used in a control word. For the detail, see Table 8.

\catcode can be set by a row of JIS X 0208 in \p\TeX, and generally by a Unicode block\footnote{up\TeX divides U+FF00–U+FFEF (Halfwidth and Fullwidth Forms) into three subblocks, and \catcode can be set by a subblock.} in up\TeX. So characters which can be used in a control word slightly differ between \p\TeX and up\TeX.

5.2 Case of Lua\TeX-ja

The role of \catcode in \p\TeX and up\TeX can be divided into the following four kinds, and Lua\TeX-ja can control these four kinds separately:

- Distinction between JAchar or ALchar is controlled by the character range, see Subsection 4.1.
- Whether the character can be used in a control word is controlled by setting \catcode to 11 (enabled) or 12 (disabled), as usual.
- Whether \texttt{jcharwidowpenalty} can be inserted before the character is controlled by the lowermost bit of the \texttt{kcatcode} parameter.
- Linebreak after a JAchar does not produce a space.

Default setting of \texttt{\catcode} of Unicode characters with Lua\TeX is slightly inconvenient for \p\TeX users to shifting to Lua\TeX-ja, because several fullwidth characters which can be used in a control word with \p\TeX, such as “１” (FULLWIDTH DIGIT ONE), cannot be used in a control word with Lua\TeX. Hence, Lua\TeX-ja changes the \texttt{\catcode} of some characters—whose line breaking class is “ID” (Ideographic) in UAX #14—, to allow these characters in the control word.

5.3 Non-kanji characters in a control word

Because the engine differ, so non-kanji JIS X 0208 characters which can be used in a control word differ in \p\TeX, in up\TeX, and in Lua\TeX-ja. Table 9 shows the difference. Except for three characters “・”, “゛”, and “゜”, Lua\TeX-ja admits more characters in a control word than up\TeX.

Difference becomes larger, if we consider non-kanji JIS X 0213 characters. For the detail, see https://github.com/h-kitagawa/kct.

6 Directions

Lua\TeX supports four \Omega-style directions: TLT, TRT, RTT and LTL. However, neither directions are not well-suited for typesetting Japanese vertically, hence we implemented vertical writing by rotating TLT-box by 90 degrees.

Lua\TeX-ja supports four directions, as shown in Table 10. The second column (yoko direction) is just horizontal writing, and the third column (tate direction) is vertical writing. The fourth column (dtou direction) is actually a hidden feature of \p\TeX. We implemented this for debugging purpose. The fifth column (utod direction) corresponds the “tate (math) direction” of \p\TeX.

Directions can be changed by \texttt{\yoko}, \texttt{\tate}, \texttt{\dtou}, \texttt{\utod}, only when the current list is null. These commands cannot be executed in unrestricted horizontal modes, nor math modes. The direction of a math formula is changed to \texttt{utod}, when the direction outside the math formula is \texttt{tate} (vertical writing).

6.1 Boxes in different direction

As in p\TeX, one can use boxes of different direction in one document. The below is an example.

```latex
\hbox{ここは横組} % yoko
\begin{tate}
\hbox{縦組}
\end{tate}
\hbox{の中に}
\begin{yoko}
\hbox{横組の内容} % yoko
\end{yoko}
\hbox{を挿入する}
\hbox{ここは横組} % yoko
```

Table 11 shows how a box is arranged when the direction inside the box and that outside the box differ.

\textbf{\wd and direction} In p\TeX, \texttt{\wd}, \texttt{\ht}, \texttt{\dp} means the dimensions of a box register with respect to the current direction. This means that the value of \texttt{\wd} etc. might differ when the current direction is different, even if \texttt{\box0} stores the same box. However, this no longer applies in Lua\TeX-ja.
Table 10. Directions supported by LuaTeX-ja

</tr>
</tbody>
</table>

Example

![Example Diagram]

(Notation used in Ω)

TLT \hspace{20.0pt} RTR, RTT \hspace{100.0pt} LBL \hspace{100.0pt} RTR

To access box dimensions with respect to current direction, one has to use the following commands instead of \wd wtc.

\ltjgetwd\langle num\rangle, \ltjgetht\langle num\rangle, \ltjgetdp\langle num\rangle

These commands return an internal dimension of \box\langle num\rangle with respect to the current direction. One can use these in \dimexpr primitive, as the followings.

\dimexpr 20.0pt, \the\ltjgetwd1701\relax, \the\ltjgetht1701

The following is an example.

\begin{verbatim}
\setbox0=\hbox{\yokoよこぐみ}
\parindent0pt
\fboxsep=0mm\fbox{\copy0}
\vbox{\hsize=20mm \yoko YOKO \the\ltjgetwd32767, \the\ltjgetht32767, \the\ltjgetdp32767.}
\vbox{\hsize=20mm \tate TATE \the\ltjgetwd32767, \the\ltjgetht32767, \the\ltjgetdp32767.}
\vbox{\hsize=20mm \dtou DTOU \the\ltjgetwd32767, \the\ltjgetht32767, \the\ltjgetdp32767.}
\vbox{\hsize=20mm \utod UTOD \the\ltjgetwd32767, \the\ltjgetht32767, \the\ltjgetdp32767.}
\end{verbatim}

\ltjsetwd\langle num\rangle=\langle dimen\rangle, \ltjsetht\langle num\rangle=\langle dimen\rangle, \ltjsetdp\langle num\rangle=\langle dimen\rangle

These commands set the dimension of \box\langle num\rangle. One does not need to group the argument \langle num\rangle; four calls of \ltjsetwd below have the same meaning.

\ltjsetwd42 20pt, \ltjsetwd42=20pt, \ltjsetwd=42 20pt, \ltjsetwd=42=20pt

6.2 Getting current direction

The direction parameter returns the current direction, and the boxdir parameter (with the argument \langle num\rangle) returns the direction of a box register \box\langle num\rangle. The returned value of these parameters are a string:

<table>
<thead>
<tr>
<th>Direction</th>
<th>yoko</th>
<th>tate</th>
<th>dtou</th>
<th>utod</th>
<th>(empty)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returned value</td>

</tr>
</thead>
<tbody>
<tr>
<td>typeset in yoko direction</td>
</tr>
<tr>
<td>---------------------------------</td>
</tr>
<tr>
<td><img src="image" alt="Diagram" /></td>
</tr>
</tbody>
</table>

$W_y = h_y + d_y,$  
$H_y = w_y,$  
$D_y = 0$ pt  

$W_T = h_T + d_T,$  
$H_T = w_T/2,$  
$D_T = w_T/2$  

$W_D = h_D + d_D,$  
$H_D = w_D,$  
$D_D = h_D$  

7 Redefined primitives by Lua\TeX\-ja

The following primitives are redefined by \texttt{Lua\TeX}-ja (using \texttt{\protect\def}), for supporting Japanese typesetting and multiple directions:

\begin{verbatim}
\leavevmode\def\DIR\{\ltjgetparameter{direction}}
\hbox{\yoko \DIR}, \hbox{\tate\DIR}, \hbox{\dtou\DIR}, \hbox{\utod\DIR}, \hbox{\tate\text{tate math: \DIR}}$

\setbox2=\hbox{\tate}\ltjgetparameter{boxdir}{2}
\end{verbatim}

\textbf{4, 5, 6, 7}
Figure 1. Redefining \vadjust primitive by Lua\TeX-ja

\makeatletter\def\ltj@stop@overwrite@primitive{\insert\vadjust/\unhbox\vcenter\fontseries}\makeatother

%% Keep the meaning of \insert, \vadjust, \/, \unhbox and \vcenter. \%\ \fontseries will still be redefined by \Lua\TeX-ja, because it is not primitive.
\usepackage{luatexja}
...
\usepackage{breqn}
...
\makeatletter\ltj@overwrite@primitive\expandafter{\insert\vadjust/\unhbox\vcenter}\makeatother

%% Redefine \insert, \vadjust, \/, \unhbox and \vcenter.

Figure 2. \ltj@stop@overwrite@primitive and \ltj@overwrite@primitive

On each primitive \langle\textit{primitive}\rangle\ in the list above, its meaning just before loading Lua\TeX-ja is backed up into \ltj@@orig\langle\textit{primitive}\rangle, and the meaning after redefinition by Lua\TeX-ja is stored in \ltj@@\langle\textit{primitive}\rangle. For example, Figure 1 shows the situation of \vadjust primitive.

7.1 Suppressing redefinitions

Sometimes redefining primitives by Lua\TeX-ja causes a problem. For example, the breqn package (v0.98k) assumes that \vadjust and \insert have their primitive meanings. So, this package cannot be loaded after Lua\TeX-ja by default.

Lua\TeX-ja version 20210517.0 has features for that problem. Namely:

- Primitives which is listed in \ltj@stop@overwrite@primitive are retain their meanings at just before loading Lua\TeX-ja.
- After loading Lua\TeX-ja, one can specify primitives to \ltj@overwrite@primitive, to redefine them by Lua\TeX-ja.

See Figure 2 for an example.

8 Font Metric and Japanese Font

8.1 \jfont

To load a font as a Japanese font (for horizontal direction), you must use the \jfont instead of \font, while \jfont admits the same syntax used in \font. Lua\TeX-ja automatically loads luaotfload package, so TrueType/OpenType fonts with features can be used for Japanese fonts:

\jfont\tradmc={IPAexMincho:script=latn;\%+trad;-kern;jfm=ujis} at 14pt
\tradmc 当/体/医/区

It is required to specify a (horizontal) JFM in at each calling of \jfont. A JFM is a Lua script which contains measurements of characters and glues/kerns that are automatically inserted for Japanese typesetting. The structure of JFM will be described in the next subsection.

22
Figure 3. Example of jfmvar key

Table 12. Differences between horizontal JFMs shipped with Lua\TeX-ja

Note that the defined control sequence (\texttt{\textbackslash \readmc} in the example above) using \texttt{\jfont} is not a font\_def token, but a macro. Hence the input like \texttt{\fontname\textbackslash \readmc} causes a error. We denote control sequences which are defined in \texttt{\jfont} by \texttt{\langle jfont\_cs \rangle}.

\textbf{Specifying JFM} The general scheme for specifying a JFM is the following:

\begin{verbatim}
\jfont\langle jfont\_cs \rangle=...;jfm=\langle JFM\ name \rangle[\{(\langle JFM\ features \rangle)\}];...;jfmvar=\langle identifier \rangle;...
\end{verbatim}

\texttt{\langle JFM\ name \rangle} The name of a (horizontal) JFM. Lua\TeX-ja searches and loads jfm-\langle JFM\ name \rangle.lua.

\texttt{\langle JFM\ features \rangle} An optional comma-separated list of JFM options. Enclosing braces (\{\}) are optional, but this does not escape any characters. The contents of this list can be accessed by a table luatexja.jfont.jfm\_feature from a JFM, at its loading. See Figure 4 for an example.

Note that any JFM files which is shipped with Lua\TeX-ja does not use this feature.

\texttt{\langle identifier \rangle} An optional string.

Lua\TeX-ja “does not distinguish” two Japanese fonts which uses same JFM and are the same size. Here “uses same JFM” means that all of \langle JFM\ name \rangle, \langle JFM\ features \rangle and \langle identifier \rangle of two fonts agree.

For example, The first “)” and “)” in Figure 3 are typeset in different real fonts. However, because they use the same JFMs and their size are same, Lua\TeX-ja inserts penalties, glues and kerns as if these two character are typeset in a same font. Namely, the glue between these characters is halfwidth, as in ”). However, this does not applies with \texttt{\F} and \texttt{\H} in Figure 3, because their \langle identifier \rangle are different.

\textbf{Horizontal JFMs} The following horizontal JFMs are shipped with Lua\TeX-ja.

\texttt{jfm-ujis.lua} A standard horizontal JFM of Lua\TeX-ja. This file is based on upnmlminr-h.tfm, a metric for UTF/OTF package that is used in up\TeX. When you are going to use the luatexja-otf package, you should use this JFM.
\begin{verbatim}
\sbox0{\texttt{\string#1}}&\sbox1{\texttt{\string#1}}&\sbox2{\texttt{\string#1}}&\sbox3{\texttt{\string#1}}\\\
\TEST\A\\\TEST\B\\\TEST\C\\\TEST\D\\
\end{verbatim}

Figure 4. Example of JFM features

\texttt{jfm-jis.lua} A counterpart for \texttt{jis.tfm}, "JIS font metric" which is widely used in \TeX. A major difference between \texttt{jfm-ujis.lua} and this \texttt{jfm-jis.lua} is that most characters under \texttt{jfm-ujis.lua} are square-shaped, while that under \texttt{jfm-jis.lua} are horizontal rectangles.

\texttt{jfm-min.lua} A counterpart for \texttt{min10.tfm}, which is one of the default Japanese font metric shipped with \TeX.

\texttt{jfm-prop.lua} A JFM for proportional typesetting. This JFM doesn’t have any information of character dimension (width, height, depth), nor glues/kerns information.

\texttt{jfm-propw.lua} Another JFM for proportional typesetting. In contrast to \texttt{jfm-prop.lua}, this JFM has informations of character height and depth.

See Table 12 for the difference among \texttt{jfm-ujis.lua}, \texttt{jfm-jis.lua}, \texttt{jfm-min.lua}.

\textbf{Using kerning information in a font} Some fonts have information for inter-glyph spacing. Lua\TeX-ja 20140324.0 or later treats kerning spaces like an italic correction; any glue and/or kern from the JFM and a kerning space can coexist. See Figure 5 for detail.

Note that in \texttt{\setmainfont} etc. which are provided by luatexja-fontspec package, kerning option is set\textit{off} (Kerning=Off) by default, because of the compatibility with previous versions of Lua\TeX-ja.

\textbf{extend and slant} The following setting can be specified as OpenType font features:

\texttt{extend=⟨extend⟩} expand the font horizontally by ⟨extend⟩.

\texttt{slant=⟨slant⟩} slant the font.

Note that Lua\TeX-ja doesn’t adjust JFMs by these \texttt{extend} and \texttt{slant} settings; one have to write new JFMs on purpose. For example, the following example uses the standard JFM \texttt{jfm-ujis.lua}, hence the letterspacing and the width of italic corrections are not correct:

\texttt{\jfont\E=HaranoAjiMincho-Regular:extend=1.5;jfm=ujis;-kern}
\texttt{\jfont\S=HaranoAjiMincho-Regular:slant=1;jfm=ujis;-kern}
\texttt{\assert{\hspace*{2pt}}} あいうえお
\texttt{\assert{\hspace*{2pt}}} あいう
\texttt{\assert{\hspace*{2pt}}} ABC

\textbf{\texttt{\textsf{ltjksp \textit{feature}}} kanjiskip\_natural, kanjiskip\_stretch, kanjiskip\_shrink keys (Page ??) makes the Lua\TeX-ja inserts not only a glue which is specified by a JFM, and also the natural width/stretch part/shrink part of \texttt{kanjiskip}. This functionality is disabled by \texttt{-ltjksp} specification, as shown in Figure 6.

\leavevmode%
\vrule\hbox to 15\zw{あ「い」う, えお}\vrule

Figure 6. \texttt{ltjksp "feature"}
8.2 \texttt{\texttt{tfont}}

\texttt{tfont} loads a font as a Japanese font for vertical direction. This command admits the same syntax as in \texttt{\texttt{font}} and \texttt{jfont}. A font defined by \texttt{\texttt{tfont}} differs the following points from that by \texttt{jfont}:

- OpenType Feature vrt2\(^2\) is automatically activated, unless vert and/or vrt2 features are explicitly activated or deactivated (as the second line in the example below).

\begin{verbatim}
\texttt{\texttt{tfont}} S=\texttt{HaranoAjiMincho-Regular:jfm=ujisv} \% vrt2 is automatically activated
\texttt{\texttt{tfont}} T=\texttt{HaranoAjiMincho-Regular:jfm=ujisv; -vert} \% vert and vrt2 are not activated
\texttt{\texttt{tfont}} U=file:ipaexm.ttf:jfm=ujisv
\end{verbatim}

\% vert is automatically activated, since this font does not have vrt2

- Sometimes vert and/or vrt2 are not activated while one specified activation of these feature. This is because the font does not define these features in current combination of script tag and language system identifier.

In this situation, Lua\TeX\-ja performs all replacements which is defined in vert feature for some scripts for some languages.

- Furthermore, a glyph is automatically rotated 90 degrees, if it is not replaced by vert feature for any script for any language, and if it is marked as ’r’ or “Tr” in UAX #50.

- \texttt{\texttt{tfont}} uses a vertical JFM instead of a horizontal JFM. Lua\TeX\-ja ships following vertical JFs:

\begin{itemize}
\item \texttt{jfm-ujisv.lua} A standard vertical JFM in Lua\TeX\-ja. This JFM is based on upnmlmnr-v.tfm, a metric for UTF/OTF package that is used in upTeX.
\item \texttt{jfm-tmin.lua} A counterpart for tmin10.tfm, which is one of the default Japanese font metric shipped with upTeX.
\end{itemize}

- If vert and/or vrt2 features are activated, one can specify \texttt{jpotf} to additional substitutions. By default, it substitutes ideographic comma/period for fullwidth comma/period, and double prime quotation marks for double quotation marks (See Figure 7). One can customize substitutions by lua function \texttt{luatexja.jfont.register_vert_replace} (see Japanese version of this manual).

8.3 Default Japanese fonts and JFs

If following commands are defined at loading Lua\TeX\-ja package, these change default Japanese fonts and JFs for them:

\begin{verbatim}
8 If the font does not define the vrt2 feature, vert is used instead.

26
\l@stdmcfont  The default Japanese font for the mincho family.
\l@stdgtfont  The default Japanese font for the gothic family.
\l@stdyokojfm The default JFM for horizontal direction.
\l@stdtatejfm The default JFM for vertical direction.

For example,
\def\l@stdmcfont{IPAMincho}
\def\l@stdgtfont{IPAGothic}

makes that IPA Mincho and IPA Gothic will be used as default Japanese fonts, instead of Harano Aji fonts.

This feature is intended for classes which use special JFMs. It is recommended to use \luatexja-preset or \luatexja-fontspec package to select standard fonts in ordinary \LaTeX{} sources.

For compatibility with earlier versions, \LaTeX{}-ja reads luatexja.cfg automatically if it is found by \LaTeX{}-ja. One should not overuse this luatexja.cfg; it will overwrite the definition of \l@stdmcfont and others.

\section{Prefix psft}

Besides "file" and "name" prefixes which are introduced in the luaotfload package, \LaTeX{}-ja adds "psft" prefix in \jfont (and \font), to specify a "name-only" Japanese font which will not be embedded to PDF. Note that these non-embedded fonts under current \LaTeX{}-ja has Identity-H encoding, and this violates the standard ISO32000-1:2008 ([10]).

OpenType font features, such as "+jp90", have no meaning in name-only fonts using "psft" prefix, because we can't expect what fonts are actually used by the PDF reader. Note that extend and slant settings (see above) are supported with psft prefix, because they are only simple linear transformations.

\subsection{cid key}

The default font defined by using psft prefix is for Japanese typesetting; it is Adobe-Japan1-7 CID-keyed font. One can specify cid key to use other CID-keyed non-embedded fonts for Chinese or Korean typesetting.

\begin{verbatim}
\jfont\testJ={psft:Ryumin-Light:cid=Adobe-Japan1-7;jfm=jis} % Japanese
\jfont\testD={psft:Ryumin-Light:jfm=jis} % default: Adobe-Japan1-7
\jfont\testC={psft:AdobeMingStd-Light:cid=Adobe-CNS1-7;jfm=jis} % Traditional Chinese
\jfont\testG={psft:SimSun:cid=Adobe-GB1-5;jfm=jis} % Simplified Chinese
\jfont\testK={psft:Batang:cid=Adobe-Korea1-2;jfm=jis} % Korean
\jfont\testKR={psft:SourceHanSerifaku9:cid=Adobe-KR-9;jfm=jis} % Korean
\end{verbatim}

Note that the code above specifies jfm=jis.lua, which is for Japanese fonts, as JFM for Chinese and Korean fonts.

At present, \LaTeX{}-ja supports only 5 values written in the sample code above. Specifying other values, e.g.,
\begin{verbatim}
\jfont\test={psft:Ryumin-Light:cid=Adobe-Japan2;jfm=jis}
\end{verbatim}

produces the following error:
\begin{verbatim}
! Package luatexja Error: bad cid key 'Adobe-Japan2'.
\end{verbatim}

This is because commands has $\@ in their names.
8.5 Structure of a JFM file

A JFM file is a Lua script which has only one function call:

```lua
luatexja.jfont.define_jfm { ...
```

Real data are stored in the table which indicated above by `{ ... }`. So, the rest of this subsection are devoted to describe the structure of this table. Note that all lengths in a JFM file are floating-point numbers in design-size unit.

```
version (optional, default value is 1)
The version JFM. Currently 1, 2, and, 3 are supported
```

```
dir (required)
The direction of JFM. 'yoko' (horizontal) or 'tate' (vertical) are supported.
```

```
zw (required)
The amount of the length of the "full-width".
```

```
zh (required)
The amount of the "full-height" (height + depth).
```

```
kanjiskip = {(natural), (stretch), (shrink)} (optional)
This field specifies the "ideal" amount of kanjiskip. As noted in Subsection 4.2, if the parameter kanjiskip is \texttt{maxdimen}, the value specified in this field is actually used (if this field is not specified in JFM, it is regarded as 0 pt). Note that (stretch) and (shrink) fields are in design-size unit too.
```

```
xkanjiskip = {(natural), (stretch), (shrink)} (optional)
Like the kanjiskip field, this field specifies the "ideal" amount of xkanjiskip.
```

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table 13. Default values of width field and other fields

**Character classes** Besides from above fields, a JFM file have several sub-tables those indices are natural numbers. The table indexed by \( i \in \omega \) stores information of character class \( i \). At least, the character class 0 is always present, so each JFM file must have a sub-table whose index is [0]. Each sub-table (its numerical index is denoted by \( i \)) has the following fields:

```
chars = {(character), ...} (required except character class 0)
This field is a list of characters which are in this character type \( i \). This field is optional if \( i = 0 \), since all JAchar which do not belong any character classes other than 0 are in the character class 0 (hence, the character class 0 contains most of JAchars). In the list, character(s) can be specified in the following form:
- a Unicode code point
- the character itself (as a Lua string, like 'あ'
- a string like 'あ*' (the character followed by an asterisk)
- several "imaginary" characters (We will describe these later.)
```

```
width = (length), height = (length), depth = (length), italic = (length) (required)
Specify the width of characters in character class \( i \), the height, the depth and the amount of italic correction. All characters in character class \( i \) are regarded that its width, height, and depth are as values of these fields. The default values are shown in Table 13.
```
Consider a Japanese character node which belongs to a character class whose the align field is 'middle'.

- The black rectangle is the imaginary body of the node. Its width, height, and depth are specified by JFM.
- Since the align field is 'middle', the “real” glyph is centered horizontally (the green rectangle) first.
- Furthermore, the glyph is shifted according to values of fields left and down. The ultimate position of the real glyph is indicated by the red rectangle.

Figure 8. The position of the real glyph (horizontal Japanese fonts)

Figure 9. The position of the real glyph (vertical Japanese fonts)

left=⟨length⟩, down=⟨length⟩, align=⟨align⟩

These fields are for adjusting the position of the “real” glyph. Legal values of align field are 'left', 'middle', and 'right'. If one of these 3 fields are omitted, left and down are treated as 0, and align field is treated as 'left'. The effects of these 3 fields are indicated in Figure 8 and Figure 9.

In most cases, left and down fields are 0, while it is not uncommon that the align field is 'middle' or 'right'. For example, setting the align field to 'right' is practically needed when the current character class is the class for opening delimiters.

kern={⟨j⟩=⟨kern⟩, ⟨j′⟩=⟨(kern), [ratio=⟨ratio⟩]⟩, ...}
glue={⟨j⟩={⟨width⟩, ⟨stretch⟩, ⟨shrink⟩, [ratio=⟨ratio⟩, ...]}, ...}

Specifies the amount of kern or glue which will be inserted between characters in character class $i$ and those in character class $j$.

⟨ratio⟩ specifies how much the glue is originated in the “right” character. It is a real number between 0 and 1, and treated as 0.5 if omitted. For example, The width of a glue between an ideographic full stop “。” and a fullwidth middle dot “・” is three-fourth of fullwidth, namely halfwidth from the ideographic full stop, and quarter-width from the fullwidth middle dot. In this case, we specify ⟨ratio⟩ to $0.25/(0.5 + 0.25) = 1/3$.

In case of glue, one can specify following additional keys in each ⟨j⟩ subtable:

priority=⟨priority⟩ An integer in [−4, 3] (treated as 0 if omitted), or a pair of these integers {⟨stretch⟩, ⟨shrink⟩} (version 2 or later). This is used only in line adjustment with priority by luatexja-adjust (see Subsection 13.3). Higher value means the glue is easy to stretch, and is also easy to shrink.

kanjiskip_natural=⟨num⟩, kanjiskip_stretch=⟨num⟩, kanjiskip_shrink=⟨num⟩

These keys specifies the amount of the natural width of kanjiskip (the stretch/shrink part, respectively) which will be inserted in addition to the original JFM glue. Default values of them are all 0.

As an example, in jfm-ujis.lua, the standard JFM in horizontal writing, we have
• Between an ordinal letter "あ" and an ideographic opening bracket, we have a glue whose natural part and shrink part are both half-width, while its stretch part is zero. However, this glue also can be stretched as much as the stretch part of kanjiskip times the value of kanjiskip_stretch key (1 in this case).

• Between an ideographic closing brackets (including the ideographic comma "、") and an ordinal letter (including an Alchar "f"), we have the same glue. Again, this glue also can be stretched as much as the stretch part of kanjiskip times the value of kanjiskip_stretch key (1 in this case).

• Between an ideographic opening bracket and an ordinal letter and between an ordinal letter and an ideographic closing bracket, we have a glue whose natural part and stretch part are both zero, while its shrink part as much as the shrink part of kanjiskip.

Hence we have the following result:

\begin{verbatim}
\leavevmode\let\V=vrule
\letjsetparameter{kanjiskip=0pt plus 5\zw}
\letjsetparameter{xkanjiskip=0pt plus 0.5\zw}
\V\hbox spread 7\zw{あ「い」う,えお」 f}\V
\vrule\hbox{あ「い」う,えお」 f}\V
\letjsetparameter{kanjiskip=0pt minus \zw}
\V\hbox spread -2.5\zw{あ「い」う,えお」 f}\V
\end{verbatim}

end_stretch=⟨kern⟩, end_shrink=⟨kern⟩ (optional, version 1 only)

end_adjust=⟨⟨kern⟩, ⟨kern⟩, ...⟩ (optional, version 2 or later)

round_threshold=⟨float⟩ (optional, version 3 or later, only available in character class 0)

■ Character to character classes We explain how the character class of a character is determined, using jfm-test.lua which contains the following:

[0] = {
  chars = { '漢' },
  align = 'left', left = 0.0, down = 0.0,
  width = 1.0, height = 0.88, depth = 0.12, italic=0.0,
},
[2000] = {
  chars = { '。', 'ヒ' },
  align = 'left', left = 0.0, down = 0.0,
  width = 0.5, height = 0.88, depth = 0.12, italic=0.0,
},

Now consider the following input/output:

\begin{verbatim}
\jfont\a-IPAexMincho;\jfm-test;+hwid
\setbox0\hbox{\a と漢}\the\wd0
\end{verbatim}

15.0pt

Now we look why the above source outputs 15 pt.

1. The character "と" is converted to its half width form "ト" by hwid feature.
2. According to the JFM, the character class of "ト" is 2000, hence its width is halfwidth.
3. The character class of "漢" is zero, hence its width is fullwidth.
4. Hence the width of \hbox equals to 15 pt.

This example shows that the character class of a character is generally determined after applying font features by luaotfload.

However, if the class determined by the glyph after application of features is zero, LuaTeX-Ja adopts the class determined by the glyph before application of features. The following input is an example.
Table 14. Commands for Japanese math fonts

<table>
<thead>
<tr>
<th>Japanese fonts</th>
<th>alphabetic fonts</th>
</tr>
</thead>
<tbody>
<tr>
<td>\jfam ∈ [0, 256)</td>
<td>\fam</td>
</tr>
<tr>
<td>jatextfont={\fam, (jfont_cs)}</td>
<td>\textfont(fam)=(font_cs)</td>
</tr>
<tr>
<td>jascriptfont={\fam, (jfont_cs)}</td>
<td>\scriptfont(fam)=(font_cs)</td>
</tr>
<tr>
<td>jascriptscriptfont={\fam, (jfont_cs)}</td>
<td>\scriptscriptfont(fam)=(font_cs)</td>
</tr>
</tbody>
</table>

1 \jfont a=HaranoAjiMincho-Regular:jfm=test;+vert
2 \a 漢。\inhibitglue 漢

Here, the character class of the ideographic full stop “。” (U+3002) is determined as follows:

1. As the case of “ヒ”，the ideographic full stop “。” is converted to its vertical form “︒” (U+FE12) by vert feature.
2. The character class of “︒”，according to the JFM is zero.
3. However, LuaTeX-ja remembers that this “︒” is obtained from “。” by font features. The character class of “。” is non-zero value, namely, 2000.
4. Hence the ideographic full stop “。” in above belongs the character class 2000.

### Imaginary characters
As described before, one can specify several “imaginary characters” in chars field. The most of these characters are regarded as the characters of class 0 in \TeX. As a result, LuaTeX-ja can control typesetting finer than \TeX. The following is the list of imaginary characters:

- `boxbdd`
  The beginning/ending of a hbox, and the beginning of a noindented (i.e., began by \noindent) paragraph. If a hbox \( b \) begins (resp. ends) a glue or kern between this “charater” and a JAchar, JAglue won’t be inserted before(resp. after) the hbox \( b \). kanjiskip and xkanjiskip around a hbox.

- `parbdd`
  The beginning of an (indented) paragraph.

- `jcharbdd`
  A boundary between JAchar and anything else.

- `alchar`, `nox_alchar`
  (version 3 or later) A boundary between JAchar and ALchar.

- `glue`
  (version 3 or later) A boundary between JAchar, and, a glue or kern.

-1 The left/right boundary of an inline math formula.

### Porting JFM from \TeX
See Japanese version of this manual.

#### 8.6 Math font family
\TeX handles fonts in math formulas by 16 font families\(^\text{10}\) , and each family has three fonts: \textfont, \scriptfont and \scriptscriptfont.

LuaTeX-ja’s handling of Japanese fonts in math formulas is similar; Table 14 shows counterparts to \TeX’s primitives for math font families. There is no relation between the value of \fam and that of \jfam; with appropriate settings, one can set both \fam and \jfam to the same value. Here \( j(font_cs) \) in the argument of jatextfont etc. is a control sequence which is defined by \jf, i.e., a horizontal Japanese font.

\(^\text{10}\) Omega, Aleph, LuaTeX and \( \varepsilon \) in \TeX\ can handles 256 families, but an external package is needed to support this in plain \TeX and LuaTeX.
8.7 Callbacks

Lua\TeX-ja also has several callbacks. These callbacks can be accessed via \texttt{luatexbase.add_to_callback} function and so on, as other callbacks.

**luatexja.load\_jfm callback**

With this callback, one can overwrite JFMs. This callback is called when a new JFM is loaded.

```lua
1 function (jfm\_info, jfm\_name)
2  return new\_jfm\_info
3 end
```

The argument \texttt{jfm\_info} contains a table similar to the table in a JFM file, except this argument has \texttt{chars} field which contains character codes whose character class is not 0.

An example of this callback is the \texttt{ltjarticle} class, with forcefully assigning character class 0 to 'parbdd' in the JFM \texttt{jfm-min.lua}.

**luatexja.define\_jfont callback**

This callback and the next callback form a pair, and you can assign characters which do not have fixed code points in Unicode to non-zero character classes. This \texttt{luatexja.define\_font} callback is called just when new Japanese font is loaded.

```lua
1 function (jfont\_info, font\_number)
2  return new\_jfont\_info
3 end
```

\texttt{jfont\_info} has the following fields, which may not overwritten by a user:

- \texttt{size} The font size specified at \texttt{\jfont} in scaled points (1 sp = \texttt{2^{-16}} pt).
- \texttt{zw, zh, kanjiskip, xkanjiskip} These are scaled value of those specified by the JFM, by the font size.
- \texttt{jfm} The internal number of the JFM.
- \texttt{var} The value of \texttt{jfm\_var} key, which is specified at \texttt{\jfont}. The default value is the empty string.
- \texttt{chars} The mapping table from character codes to its character classes.
  
  The specification \texttt{[i].chars={⟨character⟩, ...}} in the JFM will be stored in this field as \texttt{chars={⟨{character}⟩=i, ...}}.
- \texttt{char\_type} For \(i \in \omega\), \texttt{char\_type[i]} is information of characters whose class is \(i\), and has the following fields:
  
  - \texttt{width, height, depth, italic, down, left} are just scaled value of those specified by the JFM, by the font size.
  - \texttt{align} is a number which is determined from \texttt{align} field in the JFM:
    
    \[
    \begin{array}{|c|c|}
    \hline
    i & \text{('right' in JFM),} \\
    \hline
    0.5 & \text{('middle' in JFM),} \\
    0 & \text{(otherwise).} \\
    \hline
    \end{array}
    \]

  For \(i, j \in \omega\), \texttt{char\_type[i][j]} stores a kern or a glue which will be inserted between character class \(i\) and class \(j\).

The returned table \texttt{new\_jfont\_info} also should include these fields, but you are free to add more fields (to use them in the \texttt{luatexja.find\_char\_class} callback). The \texttt{font\_number} is a font number.

A good example of this and the next callbacks is the \texttt{luatexja-otf} package, supporting "AJ1-xxx" form for Adobe-Japan1 CID characters in a JFM. This callback doesn’t replace any code of Lua\TeX-ja.

**luatexja.find\_char\_class callback**

This callback is called just when Lua\TeX-ja is trying to determine which character class a character \texttt{chr\_code} belongs. A function used in this callback should be in the following form:
function (<number> char_class, <table> jfont_info, <number> chr_code)
if char_class~=0 then return char_class
else
    ....
return (<number> new_char_class or 0)
end
end

The argument char_class is the result of LuaT\TeX-ja's default routine or previous function calls in this callback, hence this argument may not be 0. Moreover, the returned new_char_class should be as same as char_class when char_class is not 0, otherwise you will overwrite the LuaT\TeX-ja's default routine.

luatexja.set_width callback
This callback is called when LuaT\TeX-ja is trying to encapsule a J\texttt{Achar} glyph\_node, to adjust its dimension and position.

function (<table> shift_info, <table> jfont_info, <table> char_type)
return <table> new_shift_info
end

The argument shift\_info and the returned new\_shift\_info have down and left fields, which are the amount of shifting down/lef\_t the character in a scaled point.

A good example is test/valign.lua. After loading this file, the vertical position of glyphs is automatically adjusted; the ratio (height : depth) of glyphs is adjusted to be that of letters in the character class 0. For example, suppose that

- The setting of the JFM: (height) = 88x, (depth) = 12x (the standard values of Japanese OpenType fonts);
- The value of the real font: (height) = 28y, (depth) = 5y (the standard values of Japanese TrueType fonts).

Then, the position of glyphs is shifted up by

\[
\frac{88x}{88x + 12x}(28y + 5y) - 28y = \frac{26}{25}y = 1.04y.
\]

9 Parameters

9.1 \texttt{\textbackslash ltjsetparameter}

As described before, \texttt{\textbackslash ltjsetparameter} and \texttt{\textbackslash ltjgetparameter} are commands for accessing most parameters of LuaT\TeX-ja. One of the main reason that LuaT\TeX-ja didn't adopted the syntax similar to that of p\TeX\ (e.g., \texttt{\textbackslash prebreakpenalty =10000}) is the position of hpack\_filter callback in the source of LuaT\TeX, see Section 14.

\texttt{\textbackslash ltjsetparameter} and \texttt{\textbackslash ltjglobalsetparameter} are commands for assigning parameters. These take one argument which is a key-value list. The difference between these two commands is the scope of assignment; \texttt{\textbackslash ltjsetparameter} does a local assignment and \texttt{\textbackslash ltjglobalsetparameter} does a global one by default. They also obey the value of \texttt{\textbackslash globaldefs}, like other assignments.

The following is the list of parameters which can be specified by the \texttt{\textbackslash ltjsetparameter} command. [\texttt{\textbackslash ces}] indicates the counterpart in p\TeX, and symbols beside each parameter has the following meaning:

- "∗": values at the end of a paragraph or a hbox are adopted in the whole paragraph or the whole hbox.
- "†": assignments are always global.

\texttt{jcharwidowpenalty=(penalty)∗ [\textbackslash jcharwidowpenalty]}

Penalty value for suppressing orphans. This penalty is inserted just after the last J\texttt{Achar} which is not regarded as a (Japanese) punctuation mark.
\texttt{kcatcode} = \{\texttt{\langle chr\_code\rangle}, \texttt{\langle natural\_number\rangle}\}\}^* \\

An additional attributes which each character whose character code is \texttt{\langle chr\_code\rangle} has. At version 20120506.0 or later, the lowermost bit of \texttt{\langle natural\_number\rangle} indicates whether the character is considered as a punctuation mark (see the description of jcharwidowpenalty above).

\texttt{prebreakpenalty} = \{\texttt{\langle chr\_code\rangle}, \texttt{\langle penalty\rangle}\}\}^* \\
Set a penalty which is inserted automatically before the character \texttt{\langle chr\_code\rangle}, to prevent a line starts from this character. For example, a line cannot started with one of closing brackets “) ”, so LuaTeX-ja sets \\
\texttt{\LaTeX}setparameter{prebreakpenalty={`)},10000}} by default.

\texttt{p \LaTeX} has following restrictions on \texttt{\prebreakpenalty} and \texttt{\postbreakpenalty}, but they don’t exist in Lua\LaTeX-ja:

\begin{itemize}
  \item Both \texttt{\prebreakpenalty} and \texttt{\postbreakpenalty} cannot be set for the same character.
  \item We can set \texttt{\prebreakpenalty} and \texttt{\postbreakpenalty} up to 256 characters.
\end{itemize}

\texttt{\postbreakpenalty} = \{\texttt{\langle chr\_code\rangle}, \texttt{\langle penalty\rangle}\}\}^* \\
Set a penalty which is inserted automatically after the character \texttt{\langle chr\_code\rangle}, to prevent a line ends with this character.

\texttt{jatextfont} = \{\texttt{\langlejfam\rangle}, \texttt{\langlejfont\_cs\rangle}\}\}^* \texttt{\textfont in \LaTeX}

\texttt{jascriptfont} = \{\texttt{\langlejfam\rangle}, \texttt{\langlejfont\_cs\rangle}\}\}^* \texttt{\scriptfont in \LaTeX}

\texttt{jascriptscriptfont} = \{\texttt{\langlejfam\rangle}, \texttt{\langlejfont\_cs\rangle}\}\}^* \texttt{\scriptscriptfont in \LaTeX}

\texttt{yjabaselineshift} = \texttt{\langle dimen\rangle}

\texttt{yalbaselineshift} = \texttt{\langle dimen\rangle} \texttt{\ybaselineshift}

\texttt{tjabaselineshift} = \texttt{\langle dimen\rangle}

\texttt{talbaselineshift} = \texttt{\langle dimen\rangle} \texttt{\tbaselineshift}

\texttt{jaxspmode} = \{\texttt{\langle chr\_code\rangle}, \texttt{\langle mode\rangle}\}\}^*

Set whether inserting \texttt{xkanjiskip} is allowed before/after a JA\texttt{Achar} whose character code is \texttt{\langle chr\_code\rangle}. The followings are allowed for \texttt{\langle mode\rangle}:

\begin{itemize}
  \item \texttt{0}, inhibit Insertion of \texttt{xkanjiskip} is inhibited before the character, nor after the character.
  \item \texttt{1}, preonly Insertion of \texttt{xkanjiskip} is allowed before the character, but not after.
  \item \texttt{2}, postonly Insertion of \texttt{xkanjiskip} is allowed after the character, but not before.
  \item \texttt{3}, allow Insertion of \texttt{xkanjiskip} is allowed both before the character and after the character. This is the default value.
\end{itemize}

This parameter is similar to the \texttt{\inhibitxspcode} primitive of \texttt{p \LaTeX}, but not compatible with \texttt{\inhibitxspcode}.

\texttt{akxspmode} = \{\texttt{\langle chr\_code\rangle}, \texttt{\langle mode\rangle}\}\}^* \texttt{\xspcode}

Set whether inserting \texttt{xkanjiskip} is allowed before/after a AL\texttt{Achar} whose character code is \texttt{\langle chr\_code\rangle}. The followings are allowed for \texttt{\langle mode\rangle}:

\begin{itemize}
  \item \texttt{0}, inhibit Insertion of \texttt{xkanjiskip} is inhibited before the character, nor after the character.
  \item \texttt{1}, preonly Insertion of \texttt{xkanjiskip} is allowed before the character, but not after.
  \item \texttt{2}, postonly Insertion of \texttt{xkanjiskip} is allowed after the character, but not before.
  \item \texttt{3}, allow Insertion of \texttt{xkanjiskip} is allowed before the character and after the character. This is the default value.
\end{itemize}
Note that parameters $\texttt{jaxspmode}$ and $\texttt{alxspmode}$ share a common table, hence these two parameters are synonyms of each other.

\begin{align*}
\text{autospacing} &= (\text{bool}) \quad [\text{\textbackslash autospacing}] \\
\text{autoxspacing} &= (\text{bool}) \quad [\text{\textbackslash autoxspacing}] \\
\text{kanjiskip} &= (\text{skip}) \quad [\text{\textbackslash kanjiskip}] \\
\text{xkanjiskip} &= (\text{skip}) \quad [\text{\textbackslash xkanjiskip}] \\
\text{differentjfm} &= (\text{mode}) \quad [\text{\textbackslash differentjfm}] \\
\text{jacharrange} &= (\text{ranges}) \quad [\text{\textbackslash jacharrange}] \\
\text{kansujichar} &= \{ (\text{digit}) \}, \{ \text{chr\_code} \} \quad [\text{\textbackslash kansujichar}] \\
\text{direction} &= (\text{dir}) \quad [\text{\textbackslash direction}] \\
\end{align*}

The default glue which inserted between two $\textbf{J}$\textsc{achars}. Changing current Japanese font does not alter this parameter, as $\text{p}$\TeX{}.

If the natural width of this parameter is $\text{\textbackslash maxdimen}$, $\text{Lua}$\TeX{}-ja uses the value which is specified in the JFM for current Japanese font (See Subsection 8.5).

As $\text{kanjiskip}$, if the natural width of this parameter is $\text{\textbackslash maxdimen}$, $\text{Lua}$\TeX{}-ja uses the value which is specified in the JFM for current Japanese font (See Subsection 8.5).

The default glue which inserted between a $\textbf{J}$\textsc{achar} and an $\textbf{A}$\textsc{lchar}. Changing current font does not alter this parameter, as $\text{p}$\TeX{}.

As $\text{kanjiskip}$, if the natural width of this parameter is $\text{\textbackslash maxdimen}$, $\text{Lua}$\TeX{}-ja uses the value which is specified in the JFM for current Japanese font (See Subsection 8.5).

Specify how glues/kerns between two $\textbf{J}$\textsc{achars} whose JFM (or size) are different. The allowed arguments are the followings:

- average, both, large, small, pleft, pright, paverage

The default value is paverage. ...

Assigning to this parameter has the same effect as $\text{\textbackslash yoko}$ (if $\langle \text{dir}\rangle = 4$), $\text{\textbackslash tate}$ (if $\langle \text{dir}\rangle = 3$), $\text{\textbackslash dtou}$ (if $\langle \text{dir}\rangle = 1$) or $\text{\textbackslash utod}$ (if $\langle \text{dir}\rangle = 11$). If the argument $\langle \text{dir}\rangle$ is not one of 4, 3, 1 nor 11, the behavior of this assignment is undefined.

\section*{9.2 $\textbackslash \ltjgetparameter$}

$\textbackslash \ltjgetparameter$ is a control sequence for acquiring parameters. It always takes a parameter name as first argument.

\begin{align*}
\text{\textbackslash \ltjgetparameter}\{\text{differentjfm}\}, \\
\text{\textbackslash \ltjgetparameter}\{\text{autospacing}\}, \\
\text{\textbackslash \ltjgetparameter}\{\text{kanjiskip}\}, \\
\text{\textbackslash \ltjgetparameter}\{\text{prebreakpenalty}\}\{\}'\} \\
\end{align*}

The return value of $\text{\textbackslash \ltjgetparameter}$ is always a string, which is outputted by $\text{tex.write()}$. Hence any character other than space " " (U+0020) has the category code 12 (other), while the space has 10 (space).

- If first argument is one of the following, no additional argument is needed.
  - $\text{jcharwidowpenalty}$, $\text{yjabaselineshift}$, $\text{yalbaselineshift}$, $\text{autospacing}$, $\text{autoxspacing}$, $\text{kanjiskip}$, $\text{xkanjiskip}$, $\text{differentjfm}$, $\text{direction}$

  Note that $\text{\textbackslash \ltjgetparameter}\{\text{autospacing}\}$ and $\text{\textbackslash \ltjgetparameter}\{\text{autoxspacing}\}$ returns 1 or 0, not true nor false.

- If first argument is one of the following, an additional argument—a character code, for example—is needed.
  - $\text{kcatcode}$, $\text{prebreakpenalty}$, $\text{postbreakpenalty}$, $\text{jaxspmode}$, $\text{alxspmode}$

35
\texttt{\textbackslash ltjgetparameter\{jaxspmode\}...} and \texttt{\textbackslash ltjgetparameter\{alxspmode\}...} returns 0, 1, 2, or 3, instead of \texttt{preonly} etc.

- \texttt{\textbackslash ltjgetparameter\{jacharrange\}\{\textit{range}\}} returns 0, 1, 2, or 3, instead of \texttt{preonly} etc.

  - For an integer \texttt{(\textit{digit})} between 0 and 9, \texttt{\textbackslash ltjgetparameter\{kansujichar\}\{\textit{digit}\}} returns the character code of the result of \texttt{kansuuji\{\textit{digit}\}}.

- \texttt{\textbackslash ltjgetparameter\{adjustdir\}} returns a integer which represents the direction of the surrounding vertical list. As \texttt{direction}, the return value 1 means \texttt{dtou} direction, 3 means \texttt{tate} direction (vertical typesetting), and 4 means \texttt{yoko} direction (horizontal typesetting).

- For an integer \texttt{(\textit{reg}num)} between 0 and 65535, \texttt{\textbackslash ltjgetparameter\{boxdir\}\{\textit{reg}num\}} returns the direction of \texttt{\textbackslash box\{\textit{reg}num\}}. If this box register is void, the returned value is zero.

  - The following parameter names \textit{cannot be specified} in \texttt{\textbackslash ltjgetparameter}.
    
    \begin{itemize}
    \item \texttt{\textbackslash jatextfont, \textbackslash jascriptfont, \textbackslash jascriptscriptfont, \textbackslash jacharrange}
    \end{itemize}

- \texttt{\textbackslash ltjgetparameter\{chartorange\}\{\textit{chr}code\}} returns the range number which \texttt{\textit{chr}code} belongs to (although there is no parameter named \texttt{chartorange}).

  - If \texttt{\textit{chr}code} is between 0 and 127, this \texttt{\textit{chr}code} does not belong to any character range. In this case, \texttt{\textbackslash ltjgetparameter\{chartorange\}\{\textit{chr}code\}} returns \texttt{-1}.

  - Hence, one can know whether \texttt{\textit{chr}code} is \texttt{JChar} or not by the following:

    \begin{quote}
    \texttt{\textbackslash ltjgetparameter\{jacharrange\}\{\textbackslash ltjgetparameter\{chartorange\}\{\textit{chr}code\}\} \% 0 if JChar, 1 if ALchar}
    \end{quote}

  - Because the returned value is string, the following conditionals do not work if \texttt{kanjiskip} (or \texttt{xkanjiskip}) has the stretch part or the shrink part.

    \begin{quote}
    \texttt{\textbackslash ifdim\textbackslash ltjgetparameter\{kanjiskip\}>\texttt{z@} \ldots \texttt{\textbackslash fi}}
    \texttt{\textbackslash ifdim\textbackslash ltjgetparameter\{xkanjiskip\}>\texttt{z@} \ldots \texttt{\textbackslash fi}}
    \end{quote}

    The correct way is using a temporary register.

    \begin{quote}
    \texttt{\textbackslash @tempskipa=\textbackslash ltjgetparameter\{kanjiskip\} \textbackslash ifdim\@tempskipa>\texttt{z@} \ldots \texttt{\textbackslash fi}}
    \texttt{\textbackslash @tempskipa=\textbackslash ltjgetparameter\{xkanjiskip\}\textbackslash ifdim\@tempskipa>\texttt{z@} \ldots \texttt{\textbackslash fi}}
    \end{quote}

\subsection{9.3 Alternative Commands to \texttt{\textbackslash ltjsetparameter}}

The basic method to set parameters of Lua\TeX{}-ja is to use \texttt{\textbackslash ltjsetparameter} or \texttt{\textbackslash ltjglobalsetparameter}. However, these commands are slow, because they parse a key-value list, so several alternative commands are used in Lua\TeX{}-ja. \textit{This subsection is not for general Lua\TeX{}-ja users.}

\textbf{Setting \texttt{kanjiskip} or \texttt{xkanjiskip}} In \texttt{ltjclasses}, every size-changing command such as \texttt{\Large} changes \texttt{\textbackslash kanjiskip} and \texttt{\textbackslash xkanjiskip}. But a simple implementation, as the code below, is slow since two key-value lists are parsed by \texttt{\textbackslash ltjsetparameter}:

\begin{verbatim}
\textbackslash ltjsetparameter\{kanjiskip=0\texttt{z@ plus .1\texttt{z@ minus .01\texttt{z@}}}
\textbackslash ifdim\@tempskipa>\texttt{z@}
  \textbackslash if@slide
    \textbackslash ltjsetparameter\{xkanjiskip=0.1em\}
  \texttt{\else}
    \textbackslash ltjsetparameter\{xkanjiskip=0.25em plus 0.15em minus 0.06em\}
  \texttt{\fi}
\texttt{\fi}
\end{verbatim}

Hence, Lua\TeX{}-ja defines more primitive commands, namely \texttt{\textbackslash ltj@setpar@global, \textbackslash ltjsetkanjiskip, and \textbackslash ltjsetxkanjiskip}. Here
and \ltjsetkanjiskip{10pt} has the same effect. The actual code of \ltjscodes is shown below:

\begin{verbatim}
\def\setkanjiskip#1{\setparameter{kanjiskip=#1}}
\ifdim\getparameter{xkanjiskip}>0
  \if@slide
    \setxkanjiskip{.1em}
  \else
    \setxkanjiskip{.25em plus .15em minus .06em}
  \fi
\fi
\end{verbatim}

Note that using \ltjsetkanjiskip or \ltjsetxkanjiskip alone, that is, without executing \ltj@setpar@global in advance, is not supported.

\section{Other Commands for plain \TeX\ and \LaTeX\ 2$\epsilon$}

\subsection{Commands for compatibility with \pT\TeX\ X}

The following commands are implemented for compatibility with \pT\TeX\ X. Note that the former five commands don't support JIS X 0213, but only JIS X 0208. The last \kansuji converts an integer into its Chinese numerals.

\begin{verbatim}
\kuten, \jis, \euc, \sjis, \ucs, \kansuji
\end{verbatim}

These six commands takes an internal integer, and returns a string.

\begin{verbatim}
\newcount\hoge
\hoge=`2423`12355, \kansuji\hoge, \jis\hoge
\kansuji1701
\end{verbatim}

To change characters of Chinese numerals for each digit, set \kansujichar parameter:

\begin{verbatim}
\ltjsetparameter{\kansujichar={1,`壹}}
\ltjsetparameter{\kansujichar={7,`漆}}
\ltjsetparameter{\kansujichar={0,`零}}
\kansuji1701
\end{verbatim}

\subsection{\inhbitglue, \disinhibitglue}

\inhbitglue suppresses the insertion of a glue/kern specified in JFM at the place. The following is an example, using a special JFM that there will be a glue between the beginning of a box and "あ", and also between "あ" and "ウ".

\begin{verbatim}
\jfont\g=HaranoAjiMincho-Regular:jfm-test \g
\bbox{\hbox{あウあ}}\inhbitglue\bbox{ウ}
\par\noindent あ1あ2あ3
\par\noindent\inhbitglue5
\par\hrule\noindent あoffice
\end{verbatim}

With the help of this example, we remark the specification of \inhbitglue:

- The call of \inhbitglue in the (internal) vertical mode is simply ignored.
- \inhbitglue does not suppress \kanjiskip or \xkanjiskip.
• The call of \inhibitglue in the (restricted) horizontal mode is only effective on the spot; does not get over boundary of paragraphs. Moreover, \inhibitglue cancels ligatures and kernings, as shown in the last line of above example.

• The call of \inhibitglue in math mode is just ignored.

\disinhibitglue suppresses the effect of \inhibitglue. In other words, \disinhibitglue allows the insertion of a glue/kern specified by JFM. If \inhibitglue and \disinhibitglue both specified at the same time, the latest one is effective. This command is added in the version 20201224.0.

Note that \disinhibitglue also cancels ligatures and kernings.

10.3 \ltjfakeboxbdd, \ltjfakeparbegin

Sometimes 'parbdd' and 'boxbdd' specifications look like "fail", especially in paragraphs inside list environments. This is because \everypar inserts some nodes such as boxes and kerns, so the "first letter" in a paragraph is in fact not the first letter.

\ltjfakeboxbdd and \ltjfakeparbegin primitives resolve this situation.

• \ltjfakeparbegin creates a node which indicates "beginning of an indented paragraph" to the insertion process of JAglue.

• \ltjfakeboxbdd creates a node which indicates "beginning/ending of a box" to the insertion process of JAglue.

As an example, the example above can be improved as follows:

1 \parindent1\zw
2 \noindent ああああああああああ\par % for comparison ああああああああああ
3 「ああああああ \par % normal paragraph ああああああああああ
4 「ああああああああああ
5 \everypar{\null} \ltjfakeparbegin
6 「ああああああああああ
7 あ% 1.25\zw (xkanjiskip at EOP)

10.4 \insertxkanjiskip, \insertkanjiskip

There are some situations which one wants to insert xkanjiskip manually. A simple approach is to use \hskip\ltjgetparameter{xkanjiskip}, but this approach has several weak points. To cope with these weak points, LuaTeX-ja defines a command \insertxkanjiskip which inserts xkanjiskip glue manually, from the version 20201224.0.

• "\insertxkanjiskip" (without any keyword) uses the value of xkanjiskip at the place.

• "\insertxkanjiskip late" (with "late" keyword) uses the value of xkanjiskip at the end of a paragraph/hbox.

See the example below.

1 \ltjsetparameter{xkanjiskip=0.25\zw}
2 あ (\% 0.5\zw (from JFM)
3 あ\insertxkanjiskip (% 0.25\zw (xkanjiskip at here)
4 あ\insertxkanjiskip late (% 0.25\zw (xkanjiskip at EOP)
5 あ% 1.25\zw (xkanjiskip at EOP) あ (あ (あ (あ a
6 \%
7 \ltjsetparameter{xkanjiskip=1.25\zw}
8 あ\insertxkanjiskip (% 1.25\zw (xkanjiskip at here)
9 あ% 1.25\zw (xkanjiskip at EOP)
10 \% At the end of the paragraph (EOP), xkanjiskip is 1.25\zw.
There is a similar command \insertkanjiskip (kanjiskip instead of xkanjiskip) is also defined. Note that any shorthand form of \insert[x]kanjiskip are not defined by LuaTeX-ja.

10.5 \ltjdeclarealtfont

Using \ltjdeclarealtfont, one can “compose” more than one Japanese fonts. This \ltjdeclarealtfont uses in the following form:

\ltjdeclarealtfont\langle base_font_cs\rangle\langle alt_font_cs\rangle\{\langle range\rangle\}

where \langle base_font_cs\rangle and \langle alt_font_cs\rangle are defined by \jfont. Its meaning is

If the current Japanese font is \langle base_font_cs\rangle, characters which belong to \langle range\rangle is typeset by another Japanese font \langle alt_font_cs\rangle, instead of \langle base_font_cs\rangle.

Here \langle range\rangle is a comma-separated list of character codes, but also accepts negative integers: \( -n \) \( (n \geq 1) \) means that all characters of character classes \( n \), with respect to JFM used by \langle base_font_cs\rangle. Note that characters which do not exist in \langle alt_font_cs\rangle are ignored.

For example, if \hoge uses jfm-ujis.lua, the standard JFM of LuaTeX-ja, then

\ltjdeclarealtfont\hoge\piyo\{3000-30FF,\ {-1}-{-1}\}

does

If the current Japanese font is \hoge, U+3000–U+30FF and characters in class 1 (ideographic opening brackets) are typeset by \piyo.

Note that specifying negative numbers needs specification like \{-1}\{-1\}, because simple “-1” is treated as the range between 0 and 1.

\gtfamily\large
\jchar\zag, \ltjchar\zag, \ltjjchar\zag
% default: Alchar
\jchar\analy, \ltjchar\analy, \ltjjchar\analy
% default: JAchar
\gchar\zag, \ltjchar\zag, \ltjjchar\zag
% Alchar unless \ltjjchar
\gchar\g, \ltjchar\g, \ltjjchar\g

11 Commands for \LaTeX

11.1 Loading Japanese fonts in \LaTeX

From version 20190107, LuaTeX-ja does not load Japanese fonts for horizontal direction and that for vertical direction at same time, to reduce the number of loaded fonts. This will save time for typesetting and memory consumption of Lua side ([11]).

- \selectfont loads (and chooses) only the Japanese font for the current direction, and does not load the Japanese font for other direction (LuaTeX-ja only detects its size and JFM, to calculate the amount of shifting the baseline).
- Direction changing commands (\yoko, \tate, \dtou, \utod) are patched to include the following process:
  
  If the Japanese font for new direction is not loaded, LuaTeX-ja loads it automatically.

Original commands are saved as \ltj@@orig@yoko etc.

- Specifying Japanese font command which is defined by \jfont, \tfont, or \DeclareFixedFont directly actually loads (and selects) the Japanese font. For example, \texttt{J\textbackslash{}chars} in \texttt{\box0} will be typeset in \texttt{\H\textgreek{OG}E}, in the following code:

% in horizontal direction (\yoko)
\DeclareFixedFont\H\textgreek{OG}E{\textgreek{JT}3}{\textgreek{g}}{m}{n}{\textgreek{12}} % JT3: for vertical direction
\H\textgreek{OG}E
\setbox0=\hbox{\tate あいう}

39
11.2 Patch for NFSS2

Japanese patch for NFSS2 in LuaTeX-Ja is based on plfonts.dtx which plays the same role in p\TeX\,2\varepsilon. We will describe commands which are not described in Subsection 3.1.

**additional dimensions**

Like p\TeX\,2\varepsilon, LuaTEX-Ja defines the following dimensions for information of current Japanese font:

- \cht (height), \cdp (depth), \cHT (sum of former two), \cvs (lineskip), \chs (equals to \cwd)

and its \texttt{\normalsize} version:

- \Cht (height), \Cdp (depth), \Cwd (width), \Cvs (equals to \baselineskip), \Chs (equals to \cwd).

Note that \cwd and \cHT may differ from \zw and \zh respectively. On the one hand the former dimensions are determined from a character whose character class is zero, but on the other hand \zw and \zh are specified by JFM.

\begin{verbatim}
\DeclareYokoKanjiEncoding{⟨encoding⟩}{⟨text-settings⟩}{⟨math-settings⟩}
\DeclareTateKanjiEncoding{⟨encoding⟩}{⟨text-settings⟩}{⟨math-settings⟩}
\end{verbatim}

In NFSS2 under LuaTEX-Ja, distinction between alphabetic fonts and Japanese fonts are only made by their encodings. For example, encodings OT1 and T1 are encodings for alphabetic fonts, and Japanese fonts cannot have these encodings. These command define a new encoding scheme for Japanese font families.

\begin{verbatim}
\DeclareKanjiEncodingDefaults{⟨text-settings⟩}{⟨math-settings⟩}
\DeclareKanjiSubstitution{⟨encoding⟩}{⟨family⟩}{⟨series⟩}{⟨shape⟩}
\DeclareErrorKanjiFont{⟨encoding⟩}{⟨family⟩}{⟨series⟩}{⟨shape⟩}{⟨size⟩}
\end{verbatim}

The above 3 commands are just the counterparts for \texttt{\DeclareFontEncodingDefaults} and others.

\begin{verbatim}
\reDeclareMathAlphabet{⟨unified-cmd⟩}{⟨al-cmd⟩}{⟨ja-cmd⟩}
\DeclareRelationFont{⟨ja-encoding⟩}{⟨ja-family⟩}{⟨ja-series⟩}{⟨ja-shape⟩}{⟨al-encoding⟩}{⟨al-family⟩}{⟨al-series⟩}{⟨al-shape⟩}
\end{verbatim}

This command sets the “accompanied” alphabetic font (given by the latter 4 arguments) with respect to a Japanese font given by the former 4 arguments.

\begin{verbatim}
\SetRelationFont
\end{verbatim}

This command is almost same as \texttt{\DeclareRelationFont}, except that this command does a local assignment, where \texttt{\DeclareRelationFont} does a global assignment.

\begin{verbatim}
\userefont{(Only) at the next call of \texttt{\selectfont}, change current alphabetic font encoding/family/... to the ‘accompanied’ alphabetic font family with respect to current Japanese font family, which was set by \texttt{\DeclareRelationFont} or \texttt{\SetRelationFont}.
\end{verbatim}

The following is an example of \texttt{\SetRelationFont} and \texttt{\userefont}:

\begin{verbatim}
\makeatletter
\SetRelationFont{JY3}{\k@family}{m}{n}{TU}{lmss}{m}{n}
% \k@family: current Japanese font family
\userefont
\end{verbatim}

\begin{verbatim}
\adjustbaseline
\end{verbatim}

In p\TeX\,2\varepsilon, \texttt{\adjustbaseline} sets \baselineskip to match the vertical center of “M” and that of “漢” in vertical typesetting:

\[
\texttt{\baselineskip} \leftarrow \frac{(h_M + d_M) - (h_\text{漢} + d_\text{漢})}{2} + d_\text{漢} - d_M,
\]

where \(h_a\) and \(d_a\) denote the height of “a” and the depth, respectively. In LuaTEX-Ja, this \texttt{\adjustbaseline} does similar task, namely setting the \texttt{\baselineskip} parameter (a Japanese character whose character class is zero is used, instead of “漢”).

40
日本国民は、正当に選挙された国会における代表者を通じて行動し、……
Furthermore, LuaTeX-ja applies patches which enables NFSS2 commands, such as \DeclareSymbolFont and \SetSymbolFont, to specify Japanese fonts as math fonts.

Specifying disablejfam option in \usepackage prevents applying these patches. Hence one cannot write Japanese characters in math mode directly if disablejfam option is specified. The code below does not work either:
\begin{verbatim}
\DeclareSymbolFont{mincho}{JY3}{mc}{m}{n}
\DeclareSymbolFontAlphabet{\mathmc}{mincho}
\end{verbatim}

\section*{11.3 Detail of \texttt{\fontfamily} command}

In this subsection, we describe when \texttt{\fontfamily{family}} changes current Japanese/alphabetic font family. Basically, current Japanese font family is changed to \texttt{\fontfamily{family}} if it is recognized as a Japanese font family, and similar with alphabetic font family. There is a case that current Japanese/alphabetic font family are both changed to \texttt{\fontfamily{family}}, and another case that \texttt{\fontfamily{family}} isn’t recognized as a Japanese/alphabetic font family either.

\begin{description}
\item[\textbf{Recognition as Japanese font family}] First, whether Japanese font family will be changed is determined in following order. This order is very similar to \texttt{\fontfamily{family}} in \LaTeXe, but we re-implemented in Lua. We use an auxiliary list \texttt{\textcopyright{N_J}}.
\begin{enumerate}
\item If the family \texttt{\fontfamily{family}} has been defined already by \texttt{\DeclareKanjiFamily}, \texttt{\fontfamily{family}} is recognized as a Japanese font family. Note that \texttt{\fontfamily{family}} need not be defined under current Japanese font encoding.
\item If the family \texttt{\fontfamily{family}} has been listed in a list \texttt{\textcopyright{N_J}}, this means that \texttt{\fontfamily{family}} is not a Japanese font family.
\item If the luatexja-fontspec package is loaded, we stop here, and \texttt{\fontfamily{family}} is not recognized as a Japanese font family.
\end{enumerate}

If the luatexja-fontspec package is not loaded, now LuaTeX-ja looks whether there exists a Japanese font encoding \texttt{\enc{family}} such that a font definition named \texttt{\enc{\fontfamily{family}}.fd} (the file name is all lowercase) exists. If so, \texttt{\fontfamily{family}} is recognized as a Japanese font family (the font definition file won’t be loaded here). If not, \texttt{\fontfamily{family}} is not a Japanese font family, and \texttt{\fontfamily{family}} is appended to the list \texttt{\textcopyright{N_J}}.

\item[\textbf{Recognition as alphabetic font family}] Next, whether alphabetic font family will be changed is determined in following order. We use auxiliary lists \texttt{\textcopyright{F_A}} and \texttt{\textcopyright{N_A}}.
\begin{enumerate}
\item If the family \texttt{\fontfamily{family}} has been listed in a list \texttt{\textcopyright{F_A}}, \texttt{\fontfamily{family}} is recognized as an alphabetic font family.
\item If the family \texttt{\fontfamily{family}} has been listed in a list \texttt{\textcopyright{N_A}}, this means that \texttt{\fontfamily{family}} is not an alphabetic font family.
\item If there exists an alphabetic font encoding such that the family \texttt{\fontfamily{family}} has been defined under it, \texttt{\fontfamily{family}} is recognized as an alphabetic font family, and to memorize this, \texttt{\fontfamily{family}} is appended to the list \texttt{\textcopyright{F_A}}.
\item Now LuaTeX-ja looks whether there exists an alphabetic font encoding \texttt{\enc{family}} such that a font definition named \texttt{\enc{\fontfamily{family}}.fd} (the file name is all lowercase) exists. If so, current alphabetic font family will be changed to \texttt{\fontfamily{family}} (the font definition file won’t be loaded here). If not, current alphabetic font family won’t be changed, and \texttt{\fontfamily{family}} is appended to the list \texttt{\textcopyright{N_A}}.
\end{enumerate}

Also, each call of \texttt{\DeclareFontFamily} after loading of LuaTeX-ja makes the second argument \texttt{\fontfamily{family}} is appended to the list \texttt{\textcopyright{F_A}}.

The above order is very similar to \texttt{\fontfamily{family}} in \LaTeXe, but more complicated (clause 3.). This is because \LaTeXe is a format however LuaTeX-ja is not, hence LuaTeX-ja does not know calls of \texttt{\DeclareFontFamily} before itself is loaded.
Table 15. strut

<td>0</td>
<td>0.7 \baselineskip</td>
<td>0.3 \baselineskip</td>
<td>\zstrut</td>
</tr>
</tbody>
</table>

Remarks Of course, there is a case that ⟨family⟩ is not recognized as a Japanese font family, nor an alphabetic font family. In this case, LuaTEX-ja treats "the argument (family) is wrong", so set both current alphabetic and Japanese font family to ⟨family⟩, to use the default family for font substitution.

11.4 Notes on \DeclareTextSymbol

From \LaTeX\ 2017/01/01, the standard encoding of Lua\LaTeX\ is changed to the \TU encoding. This means that symbols defined by T1 and TS1 encodings can be used without loading any package. To produces these symbols in alphabetic fonts in Lua\LaTeX-ja, Lua\LaTeX-ja patches \DeclareTextSymbol, and reloads tuenc.def.

Under original definition of \DeclareTextSymbol, internal commands which is defined by \DeclareTextSymbol (such as \T1\textquotedblleft) are chardef tokens. However, this no longer holds in Lua\LaTeX-ja; for example, the meaning of \TU\textquotedblleft is \ltjalchar8220.."

11.5 \strutbox

As \LaTeX\ (2017/04/08 or later), \strutbox is a macro which is expanded to one of \strutbox, \tstrutbox, and \dstrutbox (all of them are shown in Table 15), according to the current direction. Similarly, \strut now uses one of these boxes.

12 expl3 interface

This section describes expl3 interfaces provided by Lua\LaTeX-ja. All of them belong to the platex module, since they are provided for compatibility with Japanese \LaTeX. Note that commands which are marked with dagger ("∗") are additions by Lua\LaTeX-ja.

\platex_direction_yoko: \platex_direction_tate: \platex_direction_dtou:
Synonyms for \yoko, \tate and \dtou, respectively.

\platex_if_direction_yoko_p:
\platex_if_direction_yoko: {true code}{false code}
Tests if the current direction is yoko (horizontal writing).

\platex_if_direction_tate_nomath_p:∗
\platex_if_direction_tate_nomath: {true code}{false code}
Tests if the current direction is tate (vertical writing).

\platex_if_direction_tate_math_p:∗
\platex_if_direction_tate_math: {true code}{false code}
Tests if the current direction is utod.

\platex_if_direction_tate_p:
\platex_if_direction_tate: {true code}{false code}
Tests if the current direction is tate or utod.

\platex_if_direction_dtou_p:
\platex_if_direction_dtou: {true code}{false code}
Tests if the current direction is dtou.
13 Addon packages

LuaTeX-ja has several addon packages. These addons are written as \TeX packages, but luatexja-otf and luatexja-adjust can be loaded in plain LuaTeX by \input.

13.1 luatexja-fontspec

As described in Subsection 3.2, this optional package provides the counterparts for several commands defined in the fontspec package (requires fontspec v2.4). In addition to OpenType font features in the original fontspec, the following “font features” specifications are allowed for the commands of Japanese version:

\CID=(name), JFM=(name), JFM-var=(name)

These 3 keys correspond to \cid, \jfm and \jfmvar keys for \jfont and \tfont respectively. See Subsections 8.1 and 8.4 for details of \cid, \jfm and \jfmvar keys.

The \CID key is effective only when with \NoEmbed described below. The same JFM cannot be used in both horizontal Japanese fonts and vertical Japanese fonts, hence the JFM key will be actually used in YokoFeatures and TateFeatures keys.

\NoEmbed

By specifying this key, one can use “name-only” Japanese font which will not be embedded in the output PDF file. See Subsection 8.4.

\Kanjiskip=(bool)

Figure 11. An example of TateFeatures etc.
日本国民は、正当に選挙された国会における代表者を通じて行動し、われらとわれらの子孫のために、諸国民との協和による成果と、わが国国土にわたつて自由のもたらす恵沢を確保し、……

TateFeatures={⟨features⟩}, TateFont=⟨font⟩
The TateFeatures key specifies font features which are only turned on in vertical writing, such as Style=VerticalKana (vkna feature). Similarly, the TateFont key specifies the Japanese font which will be used only in vertical writing. A demonstrarion is shown in Figure 11.

YokoFeatures={⟨features⟩}
The YokoFeatures key specifies font features which are only turned on in horizontal writing. A demonstrarion is shown in Figure 11.

AltFont
As \ltjdeclarealtfont (Subsection 10.5) and \DeclareAlternateKanjiFont (Subsection 11.2), with this key, one can typeset some Japanese characters by a different font and/or using different features. The AltFont feature takes a comma-separated list of comma-separated lists, as the following:

```
AltFont = { ... 
  { Range=⟨range⟩, (features) },
  { Range=⟨range⟩, Font=⟨font name⟩, (features) },
  { Range=⟨range⟩, Font=⟨font name⟩ },
  ... 
}
```

Each sublist should have the Range key (sublist which does not contain Range key is simply ignored). A demonstrarion is shown in Figure 12.

Remark on AltFont, YokoFeatures, TateFeatures keys
In AltFont, YokoFeatures, TateFeatures keys, one cannot specify per-shape settings such as BoldFeatures. For example,

```
AltFont = { 
  { Font=HogeraMin-Light, BoldFont=HogeraMin-Bold, 
    Range="3000-"30FF, BoldFeatures={Color=FF1900} } 
}
```

does not work. Instead, one have to write

```
UprightFeatures = { 
  AltFont = { { Font=HogeraMin-Light, Range="3000-"30FF, } },
}, 
BoldFeatures = { 
  AltFont = { { Font=HogeraMin-Bold, Range="3000-"30FF, Color=FF1900 } },
}
```

On the other hand, YokoFeatures, TateFeatures and TateFont keys can be specified in each list in the AltFont key. Also, one can specify AltFont inside YokoFeatures, TateFeatures.
The value of \texttt{kanjiskip} is 0 pt\texttt{+1/5 em} in this figure, for making the difference obvious.

Figure 13. Line adjustment

Note that features which are specified in \texttt{YokoFeatures} and \texttt{TateFeatures} are always interpreted after other "direction-independent" features. This explains why \texttt{\textbackslash addfontfeatures} at line 6 in Figure 11 has no effect, because a color specification is already done in \texttt{YokoFeatures} and \texttt{TateFeatures} keys.

13.2 \texttt{luatexja-otf}

This optional package supports typesetting glyphs by specifying a CID number. The package \texttt{luatexja-otf} offers the following 2 low-level commands:

\begin{verbatim}
\texttt{\textbackslash CID\{\langle number\rangle}\}} \n\end{verbatim}

Typeset a glyph whose CID number is \langle number\rangle. If the Japanese font is neither Adobe-Japan1, Adobe-GB1, Adobe-CNS1, Adobe-Korea1, nor Adobe-KR CID-keyed font, \LaTeX{}-ja treats that \langle number\rangle is a CID number of Adobe-Japan1 character collection, and tries to typeset a "most suitable glyph".

Note that if the Japanese font is loaded using the HarfBuzz library, this \texttt{\textbackslash CID} command does not work.

\begin{verbatim}
\texttt{\textbackslash UTF\{\langle hex_number\rangle\}} \n\end{verbatim}

Typeset a character whose character code is \langle hex_number\rangle (in hexadecimal). This command is similar to \texttt{\textbackslash char\"\langle hex_number\rangle\}, but please remind remarks below.

This package automatically loads \texttt{luatexja-ajmacros.sty}, which is slightly modified version of \texttt{ajmacros.sty}\textsuperscript{11}. Hence one can use macros which are defined in \texttt{ajmacros.sty}, such as \texttt{\aj半角}.

\textbf{Remarks} Characters by \texttt{\textbackslash CID} and \texttt{\textbackslash UTF} commands are different from ordinary characters in the following points:

\begin{itemize}
  \item Always treated as \texttt{JAchars}.
  \item In vertical direction, \texttt{vert/vrt2} feature are automatically applied to characters by \texttt{\textbackslash UTF}, regardless these feature are not activated in current Japanese font.
  \item Processes for supporting other OpenType features (for example, glyph replacement and kerning) by the \texttt{luaotfload} package is not performed to these characters.
\end{itemize}

\textbf{Additional syntax of JFM} The package \texttt{luatexja-otf} extends the syntax of JFM; the entries of \texttt{chars} table in JFM now allows a string in the form '{AJ1-xxx}', which stands for the character whose CID number in Adobe-Japan1 is xxx.

This extended notation is used in the standard JFM \texttt{jfm-ujis.1ua} to typeset halfwidth Hiragana glyphs (CID 516–598) in halfwidth.

13.3 \texttt{luatexja-adjust}

(see Japanese version of this manual)

\textsuperscript{11}Useful macros by INOUE Koich\!, for the \texttt{japanese-otf} package.
13.4 luatexja-ruby

This addon package provides functionality of “ruby” (furigana) annotations using callbacks of Lua\TeX\-ja. There is no detailed manual of luatexja-ruby.sty in English. (Japanese manual is another PDF file, luatexja-ruby.pdf.)

Group-ruby By default, ruby characters (the second argument of \ruby) are attached to base characters (the first argument), as one object. This type of ruby is called group-ruby.

```
東西線ruby{妙典}{みようでん}駅は……
東西線\ruby{妙典}{みようでん}という駅……
東西線ruby{葛西}{かさい}駅は……
```

As the above example, ruby hangover is allowed on the Hiragana before/after its base characters.

Mono-ruby To attach ruby characters to each base characters (mono-ruby), one should use \ruby multiple times:

```
東西線のruby{妙}{みよう}ruby{典}{でん}駅は……
```

Jukugo-ruby Vertical bar | denotes a boundary of groups.

```
ruby{妙}{みよう}ruby{典}{でん}
妙 典駅は……
葛 西駅は……
```

If there are multiple groups in one \ruby call, A linebreak between two groups is allowed.

```
vbox{\haize=6zw}\noindent
 hbox to 2.5zw\ruby{京急}{かま}\ruby{蒲田}{けい}
```

If the width of ruby characters are longer than that of base characters, \ruby automatically selects the appropriate form among the line-head form, the line-middle form, and the line-end form.

```
vbox{\haize=8zw}\noindent
 \null kern3zw \null kern5zw
```

13.5 lltxjext.sty

\p\\\tX supplies additional macros for vertical writing in the plext package. The lltxjext package which we want to describe here is the Lua\TeX\-ja counterpart of the plext package.

\begin{tabular}<dir>[pos]{table spec} ... \end{tabular}
\begin{array}<dir>[pos]{table spec} ... \end{array}
\begin{minipage}<dir>[pos]{width} ... \end{minipage}

This option permits one of the following five values. If none of them is specified, the direction inside the environment is same as that outside the environment.

y yoko direction (horizontal writing)
\parbox<\texttt{\langle dir\rangle}>(\texttt{\langle pos\rangle})\{\langle width\rangle\}\{\langle contents\rangle\}
\parbox command is also extended by \texttt{\langle dir\rangle}.
\parbox<\texttt{\langle dir\rangle}>(\texttt{\langle width\rangle})\{\langle pos\rangle\}\{\langle contents\rangle\}
This commands typeset \langle contents\rangle in LR-mode, in \langle dir\rangle direction. If \langle width\rangle is positive, the width of the box becomes this \langle width\rangle. In this case, \langle contents\rangle will be aligned to left (when \langle pos\rangle is 1), center (c), or right (r).

\texttt{\textbackslash begin\{picture\}\langle dir\rangle}(x\_size, y\_size)(x\_offset, y\_offset)
\texttt{\textbackslash end\{picture\}}
\texttt{\textbackslash renсуじ\langle pos\rangle}\{\langle contents\rangle\}, \texttt{\textbackslash renすじskip}
\texttt{\textbackslash Kanじ\{\langle counter\_name\rangle\}}

\texttt{\textbackslash kasen\{\langle contents\rangle\}, \textbackslash bou\{\langle contents\rangle\}, \textbackslash boutenchar}

参照番号

13.6 \texttt{\textbackslash luatexja-preset}

As described in Subsection 3.3, One can load the \texttt{luatexja-preset} package to use several “presets” of Japanese fonts. This package provides functions in a part of \texttt{japanese-otf} package (changing fonts) and a part of \texttt{PXchfon} package (presets) by Takayuki Yato.

Options which are given in \texttt{\usepackage} but not described in this subsection are simply passed to the \texttt{luatexja-fontspec}. For example, the line 5 in below example is equivalent to lines 1–3.
\texttt{\textbackslash usepackage\[no-math\]\{\texttt{fontspec}\}}
\texttt{\textbackslash usepackage\[match\]\{\texttt{luatexja-fontspec}\}}
\texttt{\textbackslash usepackage\[kозука-prôn\]\{\texttt{luatexja-preset}\}}
\%
\texttt{\textbackslash usepackage\[no-math,match,kозука-prôn\]\{\texttt{luatexja-preset}\}}

13.6.1 General Options

\texttt{\textbackslash fontspec} (enabled by default)

With this option, Japanese fonts are selected using functionality of the \texttt{luatexja-fontspec} package. This means that the \texttt{fontspec} package is automatically loaded by this package.

If you need to pass some options to \texttt{fontspec}, you can load \texttt{fontspec} manually before \texttt{luatexja-preset}:
\texttt{\textbackslash usepackage\[no-math\]\{\texttt{fontspec}\}}
\texttt{\textbackslash usepackage\[\ldots\]\{\texttt{luatexja-preset}\}}

\texttt{\% if \texttt{nfssonly} option is \textit{not} specified; in this case these options are simply ignored.}
nfssonly
With this option, selecting Japanese fonts won’t be performed using the functionality of the fontspec package, but only standard NFSS2 (hence without \addfontfeatures etc.). This option is ignored when luatexja-fontspec package is loaded.

When this option is specified, fontspec and luatexja-fontspec are not loaded by default. Nevertheless, the packagefontspec can coexist with the option, as the following:
\usepackage{fontspec}
\usepackage[hiragino-pron,nfssonly]{luatexja-preset}

In this case, one can use \setmainfont etc. to select alphabetic fonts.

match
If this option is specified, usual family-changing commands such as \rmfamily, \textrm, \sffamily, ... also change Japanese font family. This option is passed to luatexja-fontspec, if fontspec option is specified.

nodeluxe (enabled by default)
The negation of deluxe option. Use one-weighted mincho and gothic font families. This means that \mcfamily\bfseries, \gtfamily\bfseries and \gtfamily\mdseries use the same font.

deluxe
Use the mincho family with three weights (light, medium, and bold), the gothic family with three weights (medium, bold, and extra bold), and rounded gothic\textsuperscript{13}. Mincho light and gothic extra bold can be by \mcfamily\ltseries and \gtfamily\ebseries, respectively.

• Some presets do not have the light weight of mincho. In this case, we substitute the medium weight for the light weight.
• luatexja-preset does not produce an error (only produces a warning), even if (one of) fonts for \mcfamily\ltseries, \gtfamily\ebseries, \mgfamily do not exist.

expert
Use horizontal/vertical kana alternates, and define a command \rubyfamily to use kana characters designed for ruby.

bold
Substitute bold series of gothic for bold series of mincho. If nodeluxe option is enabled, medium series of gothic is also changed, since we use same font for both series of gothic.

jis90, 90jis
Use JIS X 0208:1990 glyph variants if possible.

jis2004, 2004jis
Use JIS X 0213:2004 glyph variants if possible.

\texttt{jfm\_yoko=(jfm)}
Use the JFM jfm-(jfm).lua for horizontal direction, instead of jfm-ujis.lua (default JFM).

\texttt{jfm\_tate=(jfm)}
Use the JFM jfm-(jfm).lua for vertical direction, instead of jfm-ujisv.lua (default JFM).

jis Same as jfm\_yoko=jis.

Note that jis90, 90jis, jis2004 and 2004jis only affect with mincho, gothic (and, possibly rounded gothic) families defined by this package. We didn’t taken account of when more than one options among them are specified.

\textsuperscript{13}Provided by \mgfamily and \textmg, because “rounded gothic” is called maru gothic (丸ゴシック) in Japanese.
13.6.2 Presets which support multi weights

Besides bizud, haranoaji, morisawa-pro, and morisawa-pr6n presets, fonts are specified by font name, not by file name. In following tables, starred fonts (e.g. KozGo…-Regular) are used for medium series of gothic, if and only if deluxe option is specified.

kōzuka-pro Kozuka Pro (Adobe-Japan1-4) fonts.
kōzuka-pr6 Kozuka Pr6 (Adobe-Japan1-6) fonts.
kōzuka-pr6n Kozuka Pr6N (Adobe-Japan1-6, JIS04-savvy) fonts.

Kozuka Pro/Pr6N fonts are bundled with Adobe’s software, such as Adobe InDesign. There is not rounded gothic family in Kozuka fonts.

<table>
<thead>

<td>HG Maru Gothic M PRO</td>
<td>HG Maru Gothic M PRO</td>
</tr>
</tbody>
</table>

Note that HG Mincho E, HG Gothic E, HG Soei Kaku Gothic UB, and HG Maru Gothic PRO are internally specified by:

- **default** by font name (HGMinchoE, etc.).
- **jis90**, **90jis** by file name (hgrme.ttc, hgrge.ttc, hgrsgu.ttc, hgrsmp.ttf).
- **jis2004**, **2004jis** by file name (hgrme04.ttc, hgrge04.ttc, hgrsgu04.ttc, hgrsmp04.ttf).

13.6.5 Define/Use Custom Presets

From version 20170904.0, one can define new presets using \ltjnewpreset, and use them by \ltjaplypreset. These two commands can only be used in the preamble.

\ltjnewpreset\{<name>\}{<specification>}

Define new preset \(<name>\). This \(<name>\) cannot be same as other presets, options described in Subsubsection 13.6.1, nor following 11 strings:

- **mc** mc-l mc-m mc-b mc-bx gt gt-m gt-b gt-bx gt-eb mg-m

\(<specification>\) is a comma-separated list which consists of other presets and/or the following keys:

- **mc-l**(font) mincho light
- **mc-m**(font) mincho medium
- **mc-b**(font) mincho bold
- **mc-bx**(font) synonym for **mc-b**(font)
- **gt-m**(font) gothic medium
- **gt-b**(font) gothic bold
- **gt-bx**(font) synonym for **gt-b**(font)
- **gt-eb**(font) gothic extra bold
- **mg-m**(font) rounded gothic
- **mc**(font) Same as
  - **mc-l**(font), **mc-m**(font), **mc-b**(font)
- **gt**(font) Same as
  - **gt-m**(font), **gt-b**(font), **gt-eb**(font)

If deluxe is not specified at loading the package, only **mc** and **gt** keys (among above 11 keys) have a meaning.

\ltjnewpreset*\{<name>\}{<specification>}

Almost same as \ltjnewpreset. However, if \(<name>\) matches a preset which already defined, this command simply overwrite it.
\texttt{\texttt{\textbackslash ltjapplypreset\{\textit{name}\}}}  

Set Japanese font families using preset \texttt{(name)}.  

Note that \texttt{\texttt{\textbackslash ltjnewpreset}} does not "expand" the definition to define a preset. This means that one can write as the following:  

\begin{verbatim}
\texttt{\texttt{\textbackslash ltjnewpreset\{hoge\}\{piyo,mc-b=HiraMinProN-W6\}}}
\texttt{\texttt{\textbackslash ltjnewpreset\{piyo\}\{mg-m=HiraMaruProN-W4\}}}
\texttt{\texttt{\textbackslash ltjapplypreset\{hoge\}}}
\end{verbatim}

\section*{Restrictions} Presets which are defined by \texttt{\texttt{\textbackslash ltjnewpreset}} have following restrictions:  

\begin{itemize}
  \item One cannot specify non-embedded fonts (such as Ryumin-Light).
  \item Some presets, such as \texttt{ipa-hg}, have a feature that fonts are changed according to whether \texttt{90jis} or \texttt{jis2004} is specified. This feature is not usable in presets which are defined by \texttt{\texttt{\textbackslash ltjnewpreset}}.
\end{itemize}
Part III

Implementations

14 Storing Parameters

14.1 Used dimensions, attributes and whatsit nodes

Here the following is the list of dimensions and attributes which are used in Lua\TeX-ja.

\jQ (dimension) $\jQ$ is equal to $1 \ Q = 0.25$ mm, where "Q" (also called "級") is a unit used in Japanese phototypesetting. So one should not change the value of this dimension.

\jH (dimension) There is also a unit called "歯" which equals to 0.25 mm and used in Japanese phototypesetting. This $\jH$ is the same $\dimen$ register as $\jQ$.

\ltj@dimen@zw (dimension) A temporal register for the "full-width" of current Japanese font. The command $\zw$ sets this register to the correct value, and "return" this register itself.

\ltj@dimen@zh (dimension) A temporal register for the "full-height" (usually the sum of height of imaginary body and its depth) of current Japanese font. The command $\zh$ sets this register to the correct value, and "return" this register itself.

\jfam (attribute) Current number of Japanese font family for math formulas.

\ltj@curjfnt (attribute) If this attribute is a positive number, it stores the font number of current Japanese font for horizontal direction. If this attribute is negative, it means that the Japanese font for horizontal direction is not loaded—Lua\TeX-ja only knows its size and JFM.

\ltj@curtfnt (attribute) Similar to $\ltj@curjfnt$, but with current Japanese font for vertical direction.

\ltj@charclass (attribute) The character class of a JAchar. This attribute is only set on a glyph_node which contains a JAchar.

\ltj@yablshift (attribute) The amount of shifting the baseline of alphabetic fonts in scaled point ($2^{-16}$ pt).

\ltj@ykb1shift (attribute) The amount of shifting the baseline of Japanese fonts in scaled point ($2^{-16}$ pt).

\ltj@tablshift (attribute)
\ltj@tkblshift (attribute)

\ltj@autospc (attribute) Whether the auto insertion of kanjiskip is allowed at the node.

\ltj@autoxspc (attribute) Whether the auto insertion of xkanjiskip is allowed at the node.

\ltj@icflag (attribute) An attribute for distinguishing "kinds" of a node. One of the following value is assigned to this attribute:

italic (1) Kerns from italic correction (/), or from kerning information of a Japanese font. These kerns are "ignored" in the insertion process of JAglue, unlike explicit \kern.

packed (2)

kinsoku (3) Penalties inserted for the word-wrapping process (kinsoku shori) of Japanese characters.

from_jfm–(from_jfm + 63) (4–67) Glues/kerns from JFM.

kanji_skip (68), kanji_skip_jfm (69) Glues from kanjiskip.

xkanji_skip (70), xkanji_skip_jfm (71) Glues from xkanjiskip.

processed (73) Nodes which is already processed by ....
ic\_processed (74) Glues from an italic correction, but already processed in the insertion process of JAggles.

boxbdd (75) Glues/kerns that inserted just the beginning or the ending of an hbox or a paragraph.

special\_jaglue (76) Glues from \texttt{\insert[x]kanjiskip}.

\texttt{\ltj@kcat i} (attribute) Where \textit{i} is a natural number which is less than 7. These 7 attributes store bit vectors indicating which character block is regarded as a block of JAcars.

\texttt{\ltj@dir} (attribute) \texttt{dir\_node\_auto} (128)

\texttt{dir\_node\_manual} (256)

\texttt{\ltjlineendcomment} (counter)

Furthermore, Lua\TeX\-ja uses several user-defined whatsit nodes for internal processing. All those nodes except \texttt{direction} whatsits store a natural number (hence its type is 100). \texttt{direction} whatsits store a node list, hence its type is 110. Their \texttt{user\_id} (used for distinguish user-defined whatsits) are allocated by \texttt{luatexbase.newuserwhatsitid}.

\texttt{inhibitglue} Nodes for indicating that \texttt{\inhibitglue} is specified. The value field of these nodes doesn’t matter.

\texttt{stack\_marker} Nodes for Lua\TeX\-ja’s stack system (see the next subsection). The value field of these nodes is current group level.

\texttt{char\_by\_cid} Nodes for JAcars which processes by luaotfload won’t be applied, and the character code is stored in the value field. Each node of this type are converted to a \texttt{glyph\_node} after processes by luaotfload. Nodes of this type is used in \texttt{CID} and \texttt{UTF}.

\texttt{replace\_vs} Similar to \texttt{char\_by\_cid} whatsits above. These nodes are for ALchars which the callback process of luaotfload won’t be applied.

\texttt{begin\_par} Nodes for indicating beginning of a paragraph. A paragraph which is started by \texttt{\item} in list-like environments has a horizontal box for its label before the actual contents. So ...

\texttt{direction}

These whatsits will be removed during the process of inserting JAggles.

### 14.2 Stack system of Lua\TeX\-ja

**Background** Lua\TeX\-ja has its own stack system, and most parameters of Lua\TeX\-ja are stored in it. To clarify the reason, imagine the parameter \texttt{kanjiskip} is stored by a skip, and consider the following source:

```
\ltjsetparameter{kanjiskip=0pt}ふがふが.
\setbox0=\hbox{
\ltjsetparameter{kanjiskip=5pt}ほげほげ}
\box0.
ぴよぴよ
```

As described in Subsection 9.1, the only effective value of \texttt{kanjiskip} in an hbox is the latest value, so the value of \texttt{kanjiskip} which applied in the entire hbox should be 5 pt. However, by the implementation method of Lua\TeX, this “5 pt” cannot be known from any callbacks. In the \texttt{tex/packaging.w}, which is a file in the source of Lua\TeX, there are the following codes:

```
1226 void package(int c)
1227 {
1228 scaled h; /* height of box */
1229 halfword p; /* first node in a box */
1230 scaled d; /* max depth */
1231 int grp;
1232 grp = cur_group;
```

\begin{verbatim}
d = box_max_depth;
unsave();
save_ptr -= 4;
if (cur_list.mode_field == -hmode) {
  cur_box = filtered_hpack(cur_list.head_field,
  cur_list.tail_field, saved_value(1),
  saved_level(1), grp, saved_level(2));
  subtype(cur_box) = HLIST_SUBTYPE_HBOX;
}
\end{verbatim}

Notice that \texttt{unsave()} is executed before \texttt{filtered_hpack()}, where \texttt{hpack} filter callback is executed here. So "5 pt" in the above source is orphaned at \texttt{unsave()}, and hence it can’t be accessed from \texttt{hpack} filter callback.

\section*{Implementation}
The code of stack system is based on that in a post of Dev-luatex mailing list\textsuperscript{14}.

These are two \TeX{} count registers for maintaining information: \texttt{\@stack} for the stack level, and \texttt{\@group@level} for the \TeX{}’s group level when the last assignment was done. Parameters are stored in one big table named \texttt{charprop_stack_table}, where \texttt{charprop_stack_table[i]} stores data of stack level \(i\). If a new stack level is created by \texttt{\setparameter}, all data of the previous level is copied.

To resolve the problem mentioned in above paragraph "Background", Lua\TeX{}-ja uses another trick. When the stack level is about to be increased, a whatsis node whose type, subtype and value are \texttt{44 (user_defined)}, \texttt{stack_marker} and the current group level respectively is appended to the current list (we refer this node by \texttt{stack_flag}). This enables us to know whether assignment is done just inside a hbox. Suppose that the stack level is \(s\) and the \TeX{}’s group level is \(t\) just after the hbox group, then:

\begin{itemize}
  \item If there is no \texttt{stack_flag} node in the list of the contents of the hbox, then no assignment was occurred inside the hbox. Hence values of parameters at the end of the hbox are stored in the stack level \(s\).
  \item If there is a \texttt{stack_flag} node whose value is \(t + 1\), then an assignment was occurred just inside the hbox group. Hence values of parameters at the end of the hbox are stored in the stack level \(s + 1\).
  \item If there are \texttt{stack_flag} nodes but all of their values are more than \(t + 1\), then an assignment was occurred in the box, but it is done in more internal group. Hence values of parameters at the end of the hbox are stored in the stack level \(s\).
\end{itemize}

Note that to work this trick correctly, assignments to \texttt{\setparameter} and \texttt{\getparameter} have to be local always, regardless the value of \texttt{\globaldefs}. To solve this problem, we use another trick: the assignment \texttt{\directlua{tex.globaldefs=0}} is always local.

\subsection*{14.3 Lua functions of the stack system}

In this subsection, we will see how a user use Lua\TeX{}-ja’s stack system to store some data which obeys the grouping of \TeX{}.

The following function can be used to store data into a stack:
\begin{verbatim}
luatexja.stack.set_stack_table(index, <any> data)
\end{verbatim}

Any values which except \texttt{nil} and \texttt{NaN} are usable as \texttt{index}. However, a user should use only negative integers or strings as \texttt{index}. Since natural numbers are used by Lua\TeX{}-ja itself. Also, whether \texttt{data} is stored locally or globally is determined by \texttt{luatexja.isglobal} (stored globally if and only if \texttt{luatexja.isglobal == 'global'}).

Storied data can be obtained as the return value of
\begin{verbatim}
luatexja.stack.get_stack_table(index, <any> default, <number> level)
\end{verbatim}

where \texttt{level} is the stack level, which is usually the value of \texttt{\@stack}, and \texttt{default} is the default value which will be returned if no values are stored in the stack table whose level is \texttt{level}.

\subsection*{14.4 Extending Parameters}

Keys for \texttt{\setparameter} and \texttt{\getparameter} can be extended, as in \texttt{luatexja-adjust}.

\textsuperscript{14}[Dev-luatex] \texttt{tex.currentgrouplevel}, a post at 2008/8/19 by Jonathan Sauer.
\protected\def\ltj@setpar@global{% 
\relax\ifnum\globaldefs>0\directlua{luatexja.isglobal='global'}% 
\else\directlua{luatexja.isglobal=''}\fi
}\protected\def\ltjsetparameter#1{% 
\ltj@setpar@global\setkeys[ltj]{japaram}{#1}\ignorespaces}
\protected\def\ltjglobalsetparameter#1{% 
\relax\ifnum\globaldefs<0\directlua{luatexja.isglobal=''}% 
\else\directlua{luatexja.isglobal='global'}\fi% 
\setkeys[ltj]{japaram}{#1}\ignorespaces}

Figure 14. Definition of parameter setting commands

■ Setting parameters  Figure 14 shows the most outer definition of two commands, \ltjsetparameter and \ltjglobalsetparameter. Most important part is the last \setkeys, which is offered by the xkeyval package.

Hence, to add a key in \ltjsetparameter, one only have to add a key whose prefix is ltj and whose family is japaram, as the following.
\define@key[ltj]{japaram}{...}{...}
\ltjsetparameter and \ltjglobalsetparameter automatically sets luatexja.isglobal. Its meaning is the following.

\begin{equation}
\text{luatexja.isglobal} = \begin{cases}
'global' & \text{(global assignment)}, \\
'\ ' & \text{(local assignment)}.
\end{cases}
\end{equation}

This is determined not only by command name (\ltjsetparameter or \ltjglobalsetparameter), but also by the value of \globaldefs.

■ Getting parameters  \ltjgetparameter is implemented by a Lua script.

For parameters that do not need additional arguments, one only have to define a function in the table luatexja.unary_pars. For example, with the following function, \ltjgetparameter{hoge} returns a string 42.

\begin{verbatim}
1 function luatexja.unary_pars.hoge (t)
2 return 42
3 end
\end{verbatim}

Here the argument of luatexja.unary_pars.hoge is the stack level of LuaTEX-ja's stack system (see Subsection 14.2).

On the other hand, for parameters that need an additional argument (this must be an integer), one have to define a function in luatexja.binary_pars first. For example,

\begin{verbatim}
1 function luatexja.binary_pars.fuga (c, t)
2 return tostring(c) .. ', ' .. tostring(42)
3 end
\end{verbatim}

Here the first argument \(t\) is the stack level, as before. The second argument \(c\) is just the second argument of \ltjgetparameter.

For parameters that need an additional argument, one also have to execute the \TeX code like
\begin{verbatim}
1 \ltj@@decl@array@param{fuga}
\end{verbatim}
to indicate that "the parameter fuga needs an additional argument".

15  Linebreak after a Japanese Character

15.1  Reference: behavior in \texttt{p\TeX}  

In \texttt{p\TeX}, a line break after a Japanese character doesn’t emit a space, since words are not separated by spaces in Japanese writings. However, this feature isn’t fully implemented in LuaTEX-ja due to the specification of
• We omitted about category codes 9 ("ignored"), 14 ("comment"), and 15 ("invalid") from the above diagram. We also ignored the input like "~A" or "~df".

• When a character whose category code is 0 ("escape character") is seen by \TeX, the input processor scans a control sequence (scan a c.s.). These paths are not shown in the above diagram.

After that, the state is changed to State \( S \) (skipping blanks) in most cases, but to State \( M \) (middle of line) sometimes.

Figure 15. State transitions of \( \texttt{pTEX} \)'s input processor

callbacks in Lua\TeX. To clarify the difference between \( \texttt{pTEX} \) and Lua\TeX, We briefly describe the handling of a line break in \( \texttt{pTEX} \), in this subsection.

\( \texttt{pTEX} \)'s input processor can be described in terms of a finite state automaton, as that of \( \texttt{TeX} \) in Section 2.5 of [1]. The internal states are as follows:

• State \( N \): new line
• State \( S \): skipping spaces
• State \( M \): middle of line
• State \( K \): after a Japanese character

The first three states—\( N, S, \) and \( M \)—are as same as \( \texttt{TeX} \)'s input processor. State \( K \) is similar to state \( M \), and is entered after Japanese characters. The diagram of state transitions are indicated in Figure 15. Note that \( \texttt{pTEX} \) doesn't leave state \( K \) after "beginning/ending of a group" characters.

15.2 Behavior in Lua\TeX-ja

States in the input processor of Lua\TeX is the same as that of \( \texttt{TeX} \), and they can't be customized by any callbacks. Hence, we can only use \texttt{process_input_buffer} and \texttt{token_filter} callbacks for to suppress a space by a line break which is after Japanese characters.

However, \texttt{token_filter} callback cannot be used either, since a character in category code 5 ("end-of-line") is converted into a space token in \texttt{the input processor}. So we can use only the \texttt{process_input_buffer} callback. This means that suppressing a space must be done just before an input line is read.

Considering these situations, handling of an end-of-line in Lua\TeX-ja are as follows:

A character whose character code is \texttt{	extbackslash{}ljlineendcomment}\(^{15}\) is appended to an input line, before Lua\TeX actually process it, if and only if the following three conditions are satisfied:

1. The category code of \( \texttt{\texttt{\textbackslash{e}ndlinechar}} \)\(^{16}\) is 5 ("end-of-line").
2. The category code of \texttt{\textbackslash{}ljlineendcomment} itself is 14 ("comment").

\(^{15}\)Its default value is "FFFFF", so U+FFFFF is used. The category code of U+FFFFF is set to 14 ("comment") by Lua\TeX-ja.

\(^{16}\)Usually, it is \texttt{(return)} (whose character code is 13).
Table 16. Normalization of Kana Character Sequences with Combining (Semi)-voiced Sound Mark

| ツ + も → ゲ | サ + も → ガ | チ + も → カ | ケ + も → ク | ゲ + も → ケ | ジ + も → ジ |
| ツ + も → ゲ | サ + も → ガ | チ + も → カ | ケ + も → ク | ゲ + も → ケ | ジ + も → ジ |
| ツ + も → ゲ | サ + も → ガ | チ + も → カ | ケ + も → ク | ゲ + も → ケ | ジ + も → ジ |
| ツ + も → ゲ | サ + も → ガ | チ + も → カ | ケ + も → ク | ゲ + も → ケ | ジ + も → ジ |

3. The input line matches the following "regular expression":

(any char)\textbackslash{J}\text{Achar}\{\text{catcode = 1} \cup \{\text{catcode = 2}\})

\textbf{Remark}  The following example shows the major difference from the behavior of \TeX.

\begin{verbatim}
\fontspec[ligatures=TeX]{Linux Libertine O}
\textbackslash{\texttt{\textbackslash{\texttt{j}}}setparameter{\texttt{\textbackslash{j}}}acharrange={+6}} \textbackslash{\texttt{x}}
\textbackslash{\texttt{\textbackslash{\texttt{j}}}setparameter{\texttt{\textbackslash{j}}}acharrange={-6}} \textbackslash{\texttt{u}}
\textbackslash{\texttt{\textbackslash{\texttt{j}}}setparameter{\texttt{\textbackslash{j}}}autoxspacing=false}
\end{verbatim}

It is not strange that "あ" does not printed in the above output. This is because \TeX Gyre Termes does not contain "あ", and because "あ" in line 3 is considered as an \textbackslash{\texttt{\textbackslash{\texttt{A}}}char}.

Note that there is no space before "y" in the output, but there is a space before "u". This follows from following reasons:

- When line 3 is processed by \texttt{process_input_buffer} callback, "あ" is considered as an \textbackslash{\texttt{\textbackslash{\texttt{A}}}char}. Since line 3 ends with an \textbackslash{\texttt{\textbackslash{\texttt{A}}}char}, the comment character (whose character code is \textbackslash{\texttt{\textbackslash{j}}}tjlineeendcomment) is appended to this line, and hence the linebreak immediately after this line is ignored.

- When line 4 is processed by \texttt{process_input_buffer} callback, "い" is considered as an \textbackslash{\texttt{\textbackslash{\texttt{A}}}char}. Since line 4 ends with an \textbackslash{\texttt{\textbackslash{\texttt{A}}}char}, the linebreak immediately after this line emits a space.

15.3 Composition of Kana from Combining Character Sequences

In (u)\TeX, Hiragana and Katakana in the NFD form\textsuperscript{17} are normalized to precomposed characters before (u)\TeX looks into the input line. Character sequences which are involved in this normalization are shown in Table 16.

The above normalization process is also performed in Lua\TeX-ja version 20220103.0 or later, because fonts might not have these transformation as an OpenType feature.

16 Patch for the listings Package

It is well-known that the listings package outputs weird results for Japanese input. The listings package makes most of letters active and assigns output command for each letter ([2]). But Japanese characters are not included in these activated letters. For \TeX series, there is no method to make Japanese characters active; a patch \texttt{listings}([4]) resolves the problem forcibly.

In Lua\TeX-ja, the problem is resolved by using the \texttt{process_input_buffer} callback. The callback function inserts the output command (active character \texttt{\textbackslash{\texttt{\textbackslash{\texttt{A}}}char}}) before each letter above \texttt{U+0080}. This method can omits the process to make all Japanese characters active (most of the activated characters are not used in many cases).

If the listings package and Lua\TeX-ja were loaded, then the patch \texttt{lttjp-listings} is loaded automatically at \texttt{\begin{document}}.

\textsuperscript{17}namely, character sequences which contains "COMBINING KATAKANA-HIRAGANA VOICED SOUND MARK" (U+3899) and "COMBINING KATAKANA-HIRAGANA SEMI-VOICED SOUND MARK" (U+389A).
16.1 Notes and additional keys

**Variation selectors** \lltjp-listings adds two keys, namely `vsraw` and `vscmd`, which specify how variation selectors are treated in \lstlisting or other environments. Note that these additional keys are not usable in the preamble, since \lltjp-listings is loaded at `\begin{document}`.

`vsraw` is a key which takes a boolean value, and its default value is false.

- If the `vsraw` key is true, then variation selectors are “combined” with the previous character.

```latex
\begin{lstlisting}[vsraw=true]
葛 城市, 埼 装区, 葛西
\end{lstlisting}
```

- If the `vsraw` key is false, then variation selectors are typeset by an appropriate command, which is specified by the `vscmd` key. The default setting of the `vscmd` key produces the following.

```latex
\begin{lstlisting}[vsraw=false, vscmd=\ltjlistingsvsstdcmd]
葛 城市, 葛 装区, 葛西
\end{lstlisting}
```

For example, the following code is the setting of the `vscmd` key in this document.

```latex
\def\IVSA#1#2#3#4#5{\hbox to1em{\hss\textcolor{blue}{\raisebox{3.5pt}{\normalfont	tfamily\fboxsep=0.5pt\fbox{\hbox to0.75em{\hss\oalign{0#1#2\crcr#3#4#5\crcr}\hss}}}}\hss}}
\lstset{vscmd=\IVSA}
```

The default output command of variation selectors is stored in `\ltjlistingsvsstdcmd`.

**The doubleletterspace key** Even the column format is `[c]fixed, sometimes characters are not vertically aligned. The following example is typeset with `basewidth=2em`, and you’ll see the leftmost “H” are not vertically aligned.

```latex
\begin{lstlisting}
H :
H H H H :
\end{lstlisting}
```

\lltjp-listing adds the `doubleletterspace` key (not activated by default, for compatibility) to improve the situation, namely doubles inter-character space in each output unit. With this key, the above input now produces better output.

```latex
\begin{lstlisting}
H :
H H H H :
\end{lstlisting}
```

16.2 Class of characters

Roughly speaking, the listings package processes input as follows:

1. Collects *letters* and *digits*, which can be used for the name of identifiers.
2. When reading an *other*, outputs the collected character string (with modification, if needed).
3. Collects *others*.
4. When reading a *letter* or a *digit*, outputs the collected character string.
5. Turns back to 1.

By the above process, line breaks inside of an identifier are blocked. A flag `\lst@ifletter` indicates whether the previous character can be used for the name of identifiers or not.

For Japanese characters, line breaks are permitted on both sides except for brackets, dashes, etc. Hence the patch litjp-listings introduces a new flag `\lst@ifkanji`, which indicates whether the previous character is a Japanese character or not. For illustration, we introduce following classes of characters:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Other</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\lst@ifletter</code></td>
<td>T</td>
</tr>
<tr>
<td><code>\lst@ifkanji</code></td>
<td>F</td>
</tr>
</tbody>
</table>

**Meaning**
- char in an identifier
- other alphabet

<table>
<thead>
<tr>
<th>Kanji</th>
<th>Open</th>
<th>Close</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\lst@ifletter</code></td>
<td>T</td>
<td>F</td>
</tr>
<tr>
<td><code>\lst@ifkanji</code></td>
<td>T</td>
<td>T</td>
</tr>
</tbody>
</table>

**Meaning**
- most of Japanese char
- opening brackets
- closing brackets

Note that *digits* in the listings package can be Letter or Other according to circumstances.

For example, let us consider the case an Open comes after a Letter. Since an Open represents Japanese open brackets, it is preferred to be permitted to insert line break after the Letter. Therefore, the collected character string is output in this case.

The following table summarizes $5 \times 5 = 25$ cases:

<table>
<thead>
<tr>
<th>Next</th>
<th>Letter</th>
<th>Other</th>
<th>Kanji</th>
<th>Open</th>
<th>Close</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>collects</td>
<td>outputs</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Prev</td>
<td></td>
<td>outputs</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the above table,

- “outputs” means to output the collected character string (i.e., line breaking is permitted there).
- “collects” means to append the next character to the collected character string (i.e., line breaking is prohibited there).

Characters above or equal to U+0080 except Variation Selectors are classified into above 5 classes by the following rules:

- **ALchars** above or equal to U+0080 are classified as Letter.
- **JAchars** are classified in the order as follows:
  1. Characters whose `prebreakpenalty` is greater than or equal to 0 are classified as Open.
  2. Characters whose `postbreakpenalty` is greater than or equal to 0 are classified as Close.
  3. Characters that don’t satisfy the above two conditions are classified as Kanji.

The width of halfwidth kana (U+FF61–U+FF9F) is same as the width of *ALchar*; the width of the other *JAchars* is double the width of *ALchar*.

This classification process is executed every time a character appears in the `lstlisting` environment or other environments/commands.
Table 17. cid key and corresponding files

<table>
<thead>
<tr>
<th>cid key</th>
<th>name of the cache</th>
<th>used CMaps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adobe-Japan1-*</td>
<td>ltj-cid-auto-adobe-japan1.{lua.gz,luc}</td>

</tbody>
</table>

17 Cache Management of LuaTeX-ja

LuaTeX-ja creates some cache files to reduce the loading time, in a similar way to the luaotfload package:

- Cache files are usually stored in (and loaded from) `$TEXMFVAR/luatexja/`.

- In addition to caches of the text form (the extension is "\.lua.gz", because they are compressed by gzip), caches of the binary (bytecode) form are supported.
  - In loading a cache, the binary cache precedes the text form.
  - When LuaTeX-ja updates a compressed text cache `hoge\.lua.gz`, its binary version is also updated.

17.1 Use of cache

LuaTeX-ja uses the following cache:

`ltj-cid-auto-adobe-japan1.{lua.gz,luc}`

The font table of a CID-keyed non-embedded Japanese font. This is loaded in every run. It is created from three CMaps, UniJIS2004-UTF32-{H,V} and Adobe-Japan1-UCS2, and this is why these two CMaps are needed in the first run of LuaTeX-ja.

Similar caches are created as Table 17, if you specified cid key in `\jfont` to use other CID-keyed non-embedded fonts for Chinese or Korean, as in Page 27.

`ltj-kinsoku.luc`

The bytecode cache which default `kinsoku` parameters are stored.

`ltj-jisx0208.luc`

The bytecode version of `ltj-jisx0208\.lua`. This is the conversion table between JIS X 0208 and Unicode which is used in Kanji-code conversion commands for compatibility with p\TeX{}.

`ltj-ivd_aj1.luc`

The bytecode version of `ltj-ivd_aj1\.lua`.

`extra_***.{lua.gz,luc}`

This file contains some information (especially for vertical typesetting) about the font `***`.

17.2 Internal

Cache management system of LuaTeX-ja is stored in `luatexja.base` (`ltj-base\.lua`). There are four public functions for cache management in `luatexja.base`, where `<filename>` stands for the file name without suffix:

`save_cache('<filename>', <data>)`

Save a non-nil table `<data>` into a cache `<filename>`. Both the compressed text form `<filename>.lua.gz` and its binary version are created or updated.

`save_cache_luc('<filename>', <data>[, <serialized_data>])`

Same as `save_cache`, except that only the binary cache is updated. The third argument `<serialized_data>` is not usually given. But if this is given, it is treated as a string representation of `<data>`.

63
load_cache(filename, outdate)

Load the cache (filename). (outdate) is a function which takes one argument (the contents of the cache), and its return value is whether the cache is outdated.

load_cache first tries to read the binary cache (filename).luc. If its contents is up-to-date, load_cache returns the contents. If the binary cache is not found or its contents is outdated, load_cache tries to read the compressed text form (filename).lua.gz. Hence, the return value of load_cache is non-nil, if and only if the updated cache is found.

remove_cache(filename)

Remove the cache (filename).
